A SERVICE FRAMEWORK FOR LEARNING, QUERYING AND MONITORING MULTIVARIATE TIME SERIES

Chun-Kit Ngan, Alexander Brodsky and Jessica Lin Department of Computer Science, George Mason University 4400 University Drive MSN 4A5, Fairfax, Virginia 22030-4422, U.S.A.

Keywords: Service Framework, Multivariate Time Series, Parameter Learning, Decision Support.

Abstract: We propose a service framework for Multivariate Time Series Analytics (MTSA) that supports model definition, querying, parameter learning, model evaluation, monitoring, and decision recommendation. Our approach combines the strengths of both domain-knowledge-based and formal-learning-based approaches for maximizing utility over time series. More specifically, we identify multivariate time series parametric estimation problems, in which the objective function is dependent on the time points from which the parameters are learned. We propose an algorithm that guarantees to find the optimal time point(s), and we show that our approach produces results that are superior to those of the domain-knowledge-based approach and the logit regression model. We also develop MTSA data model and query language for the services of parameter learning, querying, and monitoring.

1 INTRODUCTION

Making decisions over multivariate time series is an important topic which has gained significant interest in the past decade, as two or more time series are often observed simultaneously in many fields. In business and economics, financial analysts and researchers monitor daily stock prices, weekly interest rates, and monthly price indices to analyze different states of stock markets. In medical studies, physicians and scientists measure patients' diastolic and systolic blood pressure over time and electrocardiogram tracings to evaluate the patients' health of respiratory systems. In social sciences, sociologists and demographers study annual birth rates, mortality rates, accident rates, and various crime rates to dig out hidden social problems within a community. The purpose of these measures over multivariate time series is to assist the specialists in understanding the same problem in different perspectives within particular domains. For those significant events to be identified and detected over multivariate time series, the events can lead the professionals to make better decisions and take more reasonable actions promptly. Those events may include index bottoms and tops in financial markets, irregular readings on blood pressure and pulse

anomalies on electrocardiogram, as well as low birth but high death rates in a population region. To support such decision-marking and determination over multivariate time series, we propose a service framework, Multivariate Time Series Analytics (MTSA), which consists of services for model definition, querying, parameter learning, model evaluation, monitoring, and decision recommendation. Our technical focus of this work is on the problem of event detection; namely, the parameter learning, data monitoring, and decision recommendation services.

Currently, existing approaches to identifying and detecting those interesting events can be roughly divided into two categories: domain-knowledgebased and formal-learning-based. The former relies solely on domain expert knowledge. Based on their knowledge and experiences, domain experts determine the conditions that trigger the events of interest. Consider one particular example of the timely event detection of certain conditions in the stock market, e.g., the bear market bottom, that can provide investors a valuable insight into the best investment opportunity. Such identification and detection can aid in the task of decision-making and the determination of action plans. To assist users in making better decisions and determinations, domain experts have identified a set of financial indices that

DOI: 10.5220/0003495800920101 In *Proceedings of the 13th International Conference on Enterprise Information Systems* (ICEIS-2011), pages 92-101 ISBN: 978-989-8425-54-6 Copyright © 2011 SCITEPRESS (Science and Technology Publications, Lda.) can be used to determine a bear market bottom or the "best buy" opportunity. The indices include the S&P 500 percentage decline (SPD), Coppock Guide (CG), Consumer Confidence point drop (CCD), ISM Manufacturing Survey (ISM), and Negative Leadership Composite "Distribution" (NLCD). If these indices satisfy the pre-defined, parameterized conditions, e.g., SPD < -20%, CG < 0, etc., (Stack, 2009), it signals that the best period for the investors to buy the stocks is approaching. Often these parameters may reflect some realities since they are set by the domain experts based on their past experiences, observations, intuitions, and domain knowledge. However, they are not always accurate. In addition, the parameters are static, but the problem that we deal with is often dynamic in nature. The market is constantly impacted by many unknown and uncontrollable factors from the business surroundings. Thus, this approach lacks a formal mathematical computation that dynamically learns the parameters to meet the needs of the changing environment.

An alternative approach is to utilize formal learning methods such as non-linear logit regression models. (Dougherty, 2010) The logit regression models are used to predict the occurrence of an event (0 or 1) by learning parametric coefficients of the logistic distribution function of the explanatory variables. This is done based on the historical data by applying nonlinear regression models and Maximum Likelihood Estimation (MLE). The main challenge concerning using formal learning methods to support decision-making is that they do not always produce satisfactory results, as they do not consider incorporating domain knowledge into their formal learning aproaches. Without domain experts' knoweledge, formal learning methods become computationally intensive and time consuming. The whole model building is an iterative and interactive process, including model formulation, parameter estimation, and model evaluation. Despite enormous improvements in computer software in recent years, fitting such nonlinear quantitative decision model is not a trival task, especially if the parameter learning process involves multiple explanatory variables, i.e., dimensionality. Working with high highdimensional data creates difficult challenges, a phenomenon known the "curse as of dimensionality." Specifically, the amount of observations required in order to obtain good estimates increases exponentially with the increase of dimensionality. In addition, many learning algorithms do not scale well on high dimensional data due to the high computational cost. The parameter computations by formal-learning-based approaches, e.g., logit regression model, are

complicated and costly, and they lack the consideration of integrating experts' domain knowledge into the learning process – a step that could potentially reduce the dimensionality. Clearly, both approaches, domain-knowledge-based and formal-learning-based, do not take advantage of each other to learn the optimal decision parameters, which are then used to monitor the events and make better recommendations.

To mitigate the shortcomings of the existing approaches, the proposed MTSA service framework combines the strengths of both the domainknowledge-based and the formal-learning-based approaches. The service framework supports quick implementation of services towards decision recommendation over multivariate time series. More specifically, the MTSA Model Definition Service takes the template of conditions identified by domain experts-such template consists of inequalities of values in the time sequences-and the *Learning Service* "parameterizes" it, e.g., SPD $< p_1$. The goal of the learning service is to efficiently learn parameters that maximize the objective function, e.g., earnings in our financial example. The Monitoring and Recommendation Service continuously monitors the data stream for data that satisfy the parameterized conditions, in which the parameters have been instantiated by the learning service. We also propose an extension of the relational database model and SQL, with high-level MTSA constructs to support querying, monitoring, and parameter learning.

To this end, we identify multivariate time series parametric estimation problems, in which the objective function is dependent on the time points from which the parameters are learned. With the potentially large data size and multiple variables, branch-and-bound approaches classic have exponential complexity in the worst-case scenario. We develop a new algorithm that guarantees a true optimal time point, with complexity of O(kNlogN), where N is the size of the learning data set, and k is the number of parametric time series. To demonstrate the effectiveness and the efficiency of our algorithm, we compare our method with the domain-knowledge-based approach and the logit regression model. As a proof of concept, we conduct an experiment in the financial domain, but note that our framework is applicable to solve problems in different domains. We show that our algorithm is more effective and produces results that are superior to those of the two approaches mentioned above. More specifically, in our experiments we show that our algorithm outperforms the financial experts' recommendation and the logit regression model,

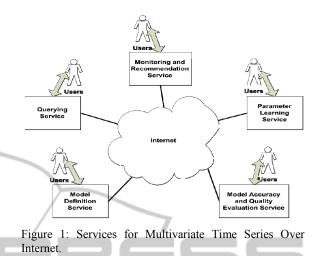

resulting in higher earnings for our imaginary investor.

The rest of the paper is organized as follows. In Section 2 we provide an overview on the MTSA service framework. We discuss the learning and monitoring services, by defining the Expert Query Parametric Estimation (EQPE) model in Section 3. Section 4 explains the domain-knowledge-inspired learning algorithm and shows the experimental evaluation on stock market data. In Section 5, we describe the MTSA data model and query language. Section 6 contains the conclusions and future work.

2 A SERVICE FRAMEWORK FOR MULTIVARIATE TIME SERIES ANALYTICS (MTSA)

Figure 1 shows a range of common services that is desirable to be offered over the internet. The MTSA Model Definition Service provides a parametric model template identified by the domain experts. In the financial example that predicts the market bottom, the model template may consist of indices such as S&P 500 percentage decline (SPD), Coppock Guide (CG), etc. These indices are associated with their respective inequality constraints, for example, SPD $< p_1$, and CG $< p_2$. Given such a parametric model template in a given domain, the Monitoring and Recommendation Service continuously screens the incoming data stream for indices that satisfy all the constraints which specify when the event of interest, e.g., the market bottom, has occurred, and recommends an action, e.g., buying stock. Note that in the traditional approach, the decision parameters p_1 and p_2 are specified by the domain experts, e.g., SPD < -20%, and CG < 0. However, using hard-set parameters cannot capture the dynamics of the rapidly changing market. The Parameter Learning Service parameterizes the template, e.g., SPD $< p_1$ and CG < p_{2} , and supports learning of the parameters from the historic time series. The accuracy of the decision parameters are ensured through the Model Accuracy and Quality Evaluation Service, which validates the prediction, i.e., market bottom, with the observed real data, and updates the model if necessary. The Querying Service allows the service developers and database programmers to express the complex information services over multivariate time series mentioned above in a high-level abstraction.

The service framework for multivariate time series analytics (MTSA) provides a medium that supports quick implementation of the services described above. The MTSA service framework is illustrated in Figure 2.

It consists of three layers: data integration, information processing, and query language. The top layer is the MTSA Model Definition and Query Language, which extends the relational model with time series and SQL with MTSA constructs. The middle layer supports the MTSA constructs including MTSA model template definition, querying, parameter learning, model evaluation, data monitoring, and decision recommendation. The bottom, Data Integration Layer, allows service providers to interact with external data services and collect time series data from heterogeneous sources, as well as from local repositories. This integration layer provides a concentric view of the collected data. The integration of the model template and the learned parameters, which may be available both locally and through external services, is also supported by the Data Integration Layer.

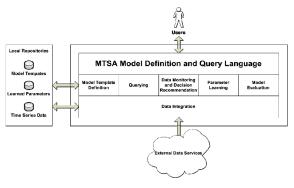

Figure 2: A Service Framework for Multivariate Time Series Analytics.

3 EXPERT QUERY PARAMETRIC ESTIMATION (EQPE) MODEL

In this section, we discuss in detail the methodologies used in the *Parameter Learning Service* and the *Monitoring and Recommendation Service* in the MTSA framework. More specifically, we review the mathematical formulations of the Expert Query Parametric Estimation (EQPE) problem and solution. We also use the examples to explain them in detail.

The goal of an EQPE problem is to find optimal values of decision parameters that maximize an objective function over historical, multivariate time series. For an EQPE problem being constructed, we need to define a set of mathematical notations and a model for it. We assume that the time domain **T** is represented by a set of natural numbers: $\mathbf{T} = \mathbf{N}$, and that we are also given a vector of n real-valued parameter variables $(p_1, p_2, ..., p_n)$.

parameter variables $(p_1, p_2, ..., p_n)$. **Definition 1.** *Time Series*: A time series S is a function S: $T \rightarrow R$, where T is the time domain, and R is the set of real numbers.

Definition 2. *Parametric Monitoring Constraint*: A parametric monitoring constraint $C(S_1(t), S_2(t), ..., S_k(t), p_1, p_2, ..., p_n)$ is a symbolic expression in terms of $S_1(t), S_2(t), ..., S_k(t), p_1, p_2, ..., p_n$, where $S_1(t), S_2(t), ..., S_k(t)$ are time series, $t \in T$ is a time point, and $(p_1, p_2, ..., p_n)$ is a vector of parameters.

We assume a constraint C written in a language that has the truth-value interpretation I: $R^k \propto R^n \rightarrow$ {True, False}, i.e., I(C($S_1(t), S_2(t), ..., S_k(t), p_1, p_2, ..., p_n$)) = True if and only if the constraint C is satisfied at the time point $t \in T$ and with the parameters $(p_1, p_2, ..., p_n) \in R^n$. In this paper, we focus on conjunctions of inequality constraints: C($S_1(t), S_2(t), ..., S_k(t), p_1, p_2, ..., p_n$) = Λ_i ($S_i(t)$ op p_i), where $op \in \{<, \leq, =, \geq, >\}$.

Definition 3. *Time Utility Function*: A time utility function U is a function U: $T \rightarrow R$.

Definition 4. Objective Function: Given a time utility function U: $T \rightarrow R$ and a parametric constraint C, an objective function O is a function O: $R^n \rightarrow R$, which maps a vector of n parameters on R^n to a real value *R*, defined as follows. For $(p_1, p_2, ..., p_n) \in R^n$, $O(p_1, p_2, ..., p_n) \stackrel{\text{def}}{=} U(t)$, where U is the utility function, and $t \in T$ is the earliest time point that satisfies C, i.e.,

(1) $S_1(t)$ $op_1 p_1 \wedge S_2(t)$ $op_2 p_2 \wedge \ldots \wedge S_n(t)$ $op_n p_n$ is satisfied, and

(2) There does not exist $0 \le t' < t$, such that $S_1(t')$ $op_1 p_1 \land S_2(t') op_2 p_2 \land \dots \land S_n(t') op_n p_n$ is satisfied. **Definition 5.** Expert Query Parametric Estimation (EQPE) Problem: An EQPE problem is a tuple $\langle S, P, C, U \rangle$, where $S = \{S_1, S_2, ..., S_k\}$ is a set of k time series, $P = \{p_1, p_2, ..., p_n\}$ is a set of n real-value parameter variables, C is a parametric constraint in S and P, and U is a time utility function.

Intuitively, a solution to an EQPE problem is an instantiation of values into the vector P of n real-value parameters that maximizes the objective O.

Definition 6. Expert Query Parametric Estimation (EQPE) Solution: A solution to the EQPE problem $\langle S, P, C, U \rangle$ is argmax $O(p_1, p_2, ..., p_n)$, i.e., the (estimated) values of parameters, $p_1, p_2, ..., p_n$, that maximize O, where O is the objective function corresponding to U.

The base time series in our financial example are shown in Table 1. We suppose that the first starting date in any time-series data set is $\mathbf{t} = \mathbf{0}$. Note that some base time series are the direct inputs, whereas some are used to derive another set of time series. For instance, the derived time series in our case study are shown in Table 2. The decision parameters used in the case study are defined in Table 3. Let us consider the following constraint \mathbf{C} as an illustration:

 $C(SPD(t), CG(t), CCD(t), ISM(t), NLCD(t), p_1, p_2, p_3, p_4, p_5) = SPD(t) < p_1 \land CG(t) < p_2 \land CCD(t) < p_3 \land ISM(t) < p_4 \land NLCD(t) > p_5$

It means that the parametric monitoring constraint C is satisfied, i.e., its interpretation is True, if the above inequalities with the decision parameters are satisfied at the time point t. The interpretation also indicates that the monitoring event occurs. We assume that the investor buys the S&P 500 index fund at the decision variable time t and sell it at the given t_s, which is the last day of the given training data set. The earning function $SP(t_S)/$ $SP(t) - 1 \in \mathbf{R}$ is the utility, which is maximized by choosing the optimal value $t \in T$, where SP(t_s) and SP(t) are the sell and buy value of the S&P 500 index fund at the time t_s and t respectively. The EQPE problem and solution for our example can be constructed by putting the considered time series, parameters, constraints, and functions to the definitions shown in Table 4.

Table 1: Base Time-Series Data.

Base Time Series S	Abbreviation
S&P 500	SP500(t)
Coppock Guide	CG(t)
Consumer Confidence	CC(t)
ISM Manufacturing Survey	ISM(t)
Negative Leadership Composite	NLC(t)

Derived Time Series S	Abbreviation
Percentage decline in SP(t) at the time point t	SPD(t)
Points drop in CC(t) at the time point t	CCD(t)
Number of consecutive days in Bear Market "DISTRIBUTIOIN" of NLC(t) at and before the time point t	NLCD(t)
Time Utility Earning at the time point t, i.e., the index fund is bought at t and sold at t _s , where t _s is the last day of the learning data set	Earning(t)

Table 3: Decision Parameters.

Parameter	Interpretation
p_1	Test if SPD(t) is less than p_1 at t.
p ₂	Test if CG(t) is less than p_2 at t.
p ₃	Test if CCD(t) is less than p_3 at t.
p ₄	Test if ISM(t) is less than p_4 at t.
p ₅	Test if NLCD(t) is greater than p_5 at t.

 Table 4: EQPE Problem and Solution Formulation for S&P 500 Index Fund.

Problem and Solution
Problem:
<s, c,="" p,="" u="">, where</s,>
$S = \{SPD, CG, CCD, ISM, NLCD\}$
$\mathbf{P} = \{\mathbf{p}_1, \mathbf{p}_2, \mathbf{p}_3, \mathbf{p}_4, \mathbf{p}_5\}$
$C = SPD(t) < p_1 \land CG(t) < p_2 \land CCD(t) < p_3 \land$
$ISM(t) < p_4 \land NLCD(t) > p_5$
$U = SP(t_s)/SP(t) - 1$
Solution:
argmax $O(p_1, p_2, p_3, p_4, p_5) \stackrel{\text{def}}{=} U(t)$

The values of the optimal decision parameters can be determined by using the learning algorithm, Checkpoint. Before explaining the Checkpoint algorithm in detail, we first review the concept of *Dominance*.

Definition 7. *Dominance* >: Given an EQPE problem $\langle S, P, C, U \rangle$ and any two time points $t, t' \in T$, we say that t' dominates t, denoted by t' > t, if the following conditions are satisfied:

(1) $0 \le t' \le t$, and

(2) $\forall (p_1, p_2, ..., p_n) \in \mathbb{R}^n$, $C(S_1(t), S_2(t), ..., S_k(t), p_1, p_2, ..., p_n) \rightarrow C(S_1(t'), S_2(t'), ..., S_k(t'), p_1, p_2, ..., p_n)$.

Intuitively, t' dominates t if for any selection of parametric values, the query constraint satisfaction at t implies the satisfaction at t'. Clearly, the dominated time points should be discarded when the optimal time point is being determined. We formally claim that:

Claim 1 - Given the conjunctions of inequality constraints, $S_1(t) op_1 p_1 \wedge S_2(t) op_2 p_2 \wedge ... \wedge S_k(t) op_k$ p_k and the two time points t', t such that $0 \le t' < t$, t' > t if and only if $S_1(t') op_1 S_1(t) \wedge S_2(t') op_2 S_2(t) \wedge ... \wedge S_k(t') op_k S_k(t)$. The proof is shown in Appendix.

For example, suppose there are three time series S_1 , S_2 , S_3 and three decision parameters p_1 , p_2 , p_3 . And the constraints are $C(S_1(t), S_2(t), S_3(t), p_1, p_2, p_3) = S_1(t) \ge p_1 \land S_2(t) \ge p_2 \land S_3(t) \le p_3$. Also assume the values for S_1 , S_2 , and S_3 at the time point t_1 , t_2 , and t_3 respectively in Table 5 shown in the next page.

In this case, the time point t_3 is dominated because there is a time point t_1 that make the inequality, $S_1(t_1) \ge S_1(t_3) \land S_2(t_1) \ge S_2(t_3) \land S_3(t_1) \le S_3(t_3)$, equal to true.

On the contrary, for all t' < t, if $S_1(t') \neg \operatorname{op}_1 S_1(t) \lor S_2(t') \neg \operatorname{op}_2 S_2(t) \lor \ldots \lor S_n(t') \neg \operatorname{op}_n S_n(t)$ is satisfied, t is not dominated by t' denoted by $t' \succ t$. Let us consider the same example above. Because $S_1(t_1) < S_1(t_2) \lor S_3(t_1) > S_3(t_2)$, t_2 is not dominated.

OGY PUBLICATIONS

4 CHECKPOINT ALGORITHM AND EXPERIMENTAL EVALUATION

Conceptually, we can search a particular set of parameters $\{p_1, p_2, ..., p_n\}$ which is at the earliest time point t that is not dominated by any t' such that the value of the objective function O is maximal among all the instantiations of values into parameters. However, the problem of this approach is that for every single parameter set at t in a learning data set, the parameter set at t has to be examined with all the previous sets of parameters at t' for checking the non-dominance before the optimal solution can be found. In fact, due to the quadratic nature, the conceptual approach is time consuming and expensive particularly if the size of the learning data set is significantly large. Instead, the Checkpoint algorithm uses the KD-tree data structure and searching algorithm to evaluate whether a time point t is dominated based on the Claim 1 for checking the non-dominance. The pseudo code of the algorithm is:

```
Input: <S, P, C, U>
Output: p[1...k] is an array of the
    optimal parameters that maximize
    the objective.
```

Data Structures:
1. N is the size of the learning data
 set.

```
2. T_{kd} is a KD tree that stores the parameter vectors that are not dominated so far.
```

```
3. MaxT is the time point that gives the maximal {\it U} so far, denoted by MaxU.
```

```
Processing:
```

```
STEP 1: \overline{T_{kd}} := \langle S_1(0), S_2(0), ..., S_k(0) \rangle;

MaxT := 0;

MaxU := U(0);
```

```
FOR t := 1 TO N - 1 DO {
STEP 2:
          Non-Dominance Test: Query the Tkd
          to find if there exists a point
          (p_1, p_2, ..., p_k) in the T_{kd}, which
          is in the range [S_1(t), \infty) \propto
          [S_2(t), \infty) \ge \dots \ge [S_k(t), \infty).
          IF (NOT AND t is not dominated
          AND U(t) > MaxU THEN Add
          <S_1(t), S_2(t), ..., S_k(t)> to T_{kd};
MaxT := t;
          MaxU := U(t); \}
         FOR i := 1 TO k DO
STEP 3:
          p[i] := S_i(MaxT);
STEP 4: RETURN p[1...k];
                                                IN
```

Clearly, the first time point is not dominated because there is no time point preceding it. Therefore, $\langle S_1(0), S_2(0), ..., S_k(0) \rangle$ can be added to T_{kd} . 0 and U(0) can be assigned to MaxT and MaxU respectively.

Using the Checkpoint algorithm step by step for the problem shown in Table 5, we can search through a particular set of parameters $\{p_1, p_2, p_3\}$ which is at the earliest time point t that is not dominated by *any t'* such that the value of the utility function U is maximal. In STEP 1, the $\langle S_l(t_l) \rangle$, $S_2(t_1)$, $S_3(t_1)$ is added to the T_{kd} since it is the first time point. Then t_1 and $U(t_1)$ are assigned to MaxT and MaxU respectively. In STEP 2, t₂ is not dominated because $S_1(t_1) < S_1(t_2) \land S_2(t_1) > S_2(t_2) \land$ $S_3(t_1) > S_3(t_2)$ does not satisfy the Claim 1. However, t_3 is dominated because $S_1(t_1) > S_1(t_3) \land S_2(t_1) > S_2(t_3)$ $\wedge S_3(t_1) < S_3(t_3)$ does satisfy the Claim 1. $< S_1(t_2)$, $S_2(t_2)$, $S_3(t_2)$ is added to the T_{kd} because t_2 is not dominated and $U(t_2) > U(t_1)$. Thus t_2 and $U(t_2)$ are assigned to MaxT and MaxU respectively. In STEP **3**, $p[1] := S_1(MaxT)$, $p[2] := S_2(MaxT)$, and p[3] := $S_3(MaxT)$ in the for-loop statement. In STEP 4, the algorithm returns 25, 15, and 2.

The time complexity for the range search and insertion of a parameter vector in the T_{kd} tree is $O(k\log N)$ respectively.

Theorem 1: For N parameter vectors in the data set, the Checkpoint algorithm correctly computes an EQPE solution, i.e., $argmax O(p_1, p_2, p_3, p_4, p_5)$, where O is the objective function of the EQPE problem, with the complexity $O(kN\log N)$. The proof of the theorem is shown in Appendix.

Using the Checkpoint algorithm, we can obtain the optimal decision parameters and the maximal earning from the training data set for the financial problem shown in Table 6. The time complexity of the MLE for the logit regression model is $O(k^2N)$, where k is the number of decision parameters, and N is the size of the learning data set. For the Checkpoint algorithm, the complexity is O(kNlogN). Using the decision parameters from the financial expert (i.e., -20%, 0, -30, 45, 180 days), the logit regression model, and the Checkpoint algorithm, the "Best Buy" opportunities in stock and their earnings are shown in Table 7. Note that the Checkpoint algorithm considerably outperforms both the financial expert's criteria and the logit regression model.

Table 5: Values of S_1 , S_2 , S_3 , and U at the time point t_1 , t_2 , and t_3 .

Time	S ₁	S ₂	S ₃	U
t ₁	13	27	3	10
t ₂	25	15	2	200
t ₃	10	20	5	150

Table 6: Optimal Decision Parameters and Maximum Earning (%) from the Learning Data Set¹.

\mathbf{p}_1	p ₂	p ₃	p_4	p ₅	O(p ₁ ,p ₂ ,p ₃ ,p ₄ ,p ₅)
-29.02	- 20.01	- 26.61	49	70	53.37

Table 7: Investors' Earning of the S&P 500 Index Fund from the Test Data Set².

Decision Approach	Best Buy	S&P 500 Index	Earning %
Financial Expert's Criteria	10/09/08	909.92	1.03
Logit Regression Model	11/26/08	887.68	3.56
Checkpoint Algorithm with Financial Expert's Template	03/10/09	719.6	27.8

1. The learning data set is from 06/01/1997 to 06/30/2005.

2. The test data set is from 07/01/2005 to 06/30/2009 that is the sell date of the fund with the value of 919.32.

5 MTSA DATA MODEL AND QUERY LANGUAGE

5.1 Data Model

The time-series (TS) data model is an extension of the relational model with specialized schemas. A time-series schema is of the form TSname(T:Time, Vname:Vtype), where Time and Vtype are data types, Vtype is either Real or Integer, and TSname and Vname are names chosen by users.

A time-event (TE) schema is of the form TEname(T:Time, Ename:Binary), where Binary is the binary type corresponding to the domain $\{0,1\}$, and TEname and Ename are names chosen by users.

A TS database schema is a set of relational schemas which may include (specific) TS and/or TE schemas.

A TS tuple over a schema TSname(T:Time, Vname:Vtype) is a relational tuple over that schema, i.e., a mapping m: {T, Vname} \rightarrow Dom(Time) x Dom(Vtype), such that m(T) \in Dom(Time) and m(Vname) \in Dom(Vtype).

A TE tuple over a similar schema TEname(T:Time, Ename:Binary) is a mapping m: $\{T, Ename\} \rightarrow Dom(Time) \times Dom(Binary), such that m(T) \in Dom(Time) and m(Ename) \in Dom(Binary).$

Let us consider our financial example. In the market-bottom scenario, the service provider can use the querying service to create the base, derived, and related time-series tables as inputs and store them in the database. The base time-series tables are SP500(T, Index), CG(T, Index), CC(T, Index), ISM(T, Index), and NLC(T, Index).

5.2 Querying Service

Using the base time series tables, we can generate derived time series tables (if any) by the traditional SQLs. In our case study, some derived time series tables, e.g., SPD(t), CCD(t), etc., are:

```
CREATE
         VIEW SPD AS (
SELECT
         After.T, After.Average /
         Before.Average - 1 AS Value
FROM (SELECT SP1.T, AVG(SP2.Index)
         AS Average

         AND CC1.T - 156 >= 0
         GROUP BY CC1.T) Before
WHERE After.T = Before.T);
```

5.3 Monitoring and Recommendation Service

Using the monitoring and recommendation service over the new incoming data, the financial analyst can recommend the investors whether or not they should buy the stock. In our example, the input parametric time series tables for monitoring are SPD(T, Value), CG(T, Index), CCD(T, Value), ISM(T, Index), and NLCD(T, Value). The monitoring and recommendation service can be expressed by a monitoring view and executed by the MONITOR command.

```
CREATE VIEW MarketBottomTable AS (
   SELECT SPD.T, (CASE WHEN SPD.Value <
                  PR.p_1 AND CG.Index < PR.p_2
                  AND CCD.Value < PR.p_3 AND
                  ISM.Index < PR.p4 AND
                  NLCD.Value > PR.p<sub>5</sub> THEN '1'
                  ELSE '0' END) AS MB
   FROM SPD, CG, CCD, ISM, NLCD,
        Para PR
   WHERESPD.T = CG.T AND CG.T =
   CCD.T AND CCD.T = ISM.T AND
                                       ISM.T =
NLCD.T);
  CREATE VIEW
  MB Monitoring Recommendation
   AS (SELECT MBT.T, (CASE WHEN MBT.MB
```

```
AS (SELECT MBT.T, (CASE WHEN MBT.MB
= `1' THEN `Market
Bottom Is Detected.
Buy Stock Is
Recommended.'
END) AS Action
FROM MarketBottomTable MBT);
```

MONITOR MB Monitoring Recommendation;

where Para is a table to store the decision parameters, e.g., $p_1 = -20$, $p_2 = 0$, $p_3 = -30$, $p_4 = 45$, and $p_5 = 180$. If the parametric monitoring constraint in the CASE WHEN clause is satisfied at the current time point t, the value of the attribute "MB" dedicates "1". The service then recommends the financial analysts to buy the index fund for the investors since the market bottom is predicted.

5.4 Parameter Learning Service

As we discussed, the expert's suggested parameters (-20. 0, -30, 45, 180) are not accurate enough to monitor the dynamic financial market at all time; thus, the parameter learning service should be adopted by expressing as follows:

```
Step 1: Store base TS tables, e.g.,
SP500, CG, CC, ISM, and NLC, in
          the database.
    2: Define SQL views for derived TS tables, e.g, SPD, CCD,
Step 2:
 etc., shown in Section 5.2.
Step 3: Create a parameter table
     which stores the optimal
 decision parameters.
         CREATE VIEW Para (
             p<sub>1</sub> REAL,
             p<sub>2</sub> REAL,
             p₃ REAL,
             p<sub>4</sub> REAL,
             p<sub>5</sub> REAL);
Step 4: Create a TS view for the
      time utility.
         CREATE VIEW Earning AS (SELECT
         SP1.T,
           ((Last.Index/SP1.Index
         1) * 100) AS Percent FROM SP500
         SP1.
           (SELECT SP2.Index
           FROM SP500 SP2
           WHERE SP2.T >= ALL
           (SELECT SP3.T
          FROM SP500 SP3)) Last);
Step 5:
         Create a learning event and
 then execute the event
 construct to learn the
 parameters.
          CREATE EVENT
          LearnMarketBottomParameter (
                LEARN Para PR
                 FOR MAXIMIZE E.Percent
                 WITH SPD.Value < PR.p1 AND
                 CG.Index < PR.p_2 AND
```

CCD.Value < PR.p₃ AND

ISM.Index < PR.p4 AND NLCD.Value > PR.p5 FROM SPD, CG, CCD, ISM, NLCD, Earning E WHERE SPD.T = CG.T AND CG.T = CCD.T AND CCD.T = ISM.T AND ISM.T = NLCD.T AND NLCD.T = E.T;)

EXECUTE LearnMarketBottomParameter;

When the event "LearnMarketBottomParameter" is executed, the command "LEARN" will call for the Checkpoint algorithm to solve the corresponding EQPE problem and will put its solution in the Para table, where all parameters, e.g., p_1 , p_2 , p_3 , p_4 , and p_5 are instantiated with optimal values.

6 CONCLUSIONS AND FUTURE WORK

To the best of our knowledge, this is the first paper to propose a service framework for multivariate time series analytics that provides model definition, querying, parameter learning, model evaluation, monitoring, and decision recommendation over multivariate time series data. The parameter learning services combine the strengths of both domainknowledge-based and formal-learning-based approaches for maximizing utility over multivariate time series. It includes a mathematical model and a learning algorithm for solving Expert Query Parametric Estimation problems. Using the framework, we conduct a preliminary experiment in the financial domain to demonstrate that our model and algorithm are more effective and produce results that are superior to the two approaches mentioned above. We also develop MTSA data model and query language for the services of querying, monitoring, and parameter learning. There are still many open research questions, for example, what models can capture different types of events and how those events impact the services that the framework provides.

APPENDIX

Claim 1 - Given the conjunctions of inequality constraints, $S_1(t) op_1 p_1 \wedge S_2(t) op_2 p_2 \wedge ... \wedge S_k(t) op_k$ p_k and the two time points t', t such that $0 \le t' < t$, t' > t if and only if $S_1(t') op_1 S_1(t) \wedge S_2(t') op_2 S_2(t) \wedge ... \wedge S_k(t') op_k S_k(t)$.

Proof:

Without loss of generality, we assume that $op_i =$ " \leq ", for all $1 \leq i \leq k$. It is because " \geq " can be replaced with \leq by changing a corresponding time series $S_i(t)$ to - $S_i(t)$. For $op_i =$ "=", we can use the conjunction with both \geq and \leq .

If Direction:

Assume that $S_1(t') \leq S_1(t) \wedge S_2(t') \leq S_2(t) \wedge \dots \wedge S_k(t') \leq S_k(t)$. For any $(p_1, p_2, \dots, p_k) \in \mathbb{R}^k$ and every i = 1, 2, ..., k, if $S_1(t) \leq p_1$, then $S_1(t') \leq p_1$ because $S_1(t') \leq S_1(t)$. Therefore, $S_1(t) \leq p_1 \wedge S_2(t) \leq p_2 \wedge \dots \wedge S_k(t') \leq p_k \rightarrow S_1(t') \leq p_1 \wedge S_2(t') \leq p_2 \wedge \dots \wedge S_k(t') \leq p_k$ and then $t' \succ t$.

Only If Direction:

Assume that t' > t. Then $S_1(t) \le p_1 \land S_2(t) \le p_2 \land$... $\land S_k(t) \le p_k \rightarrow S_1(t') \le p_1 \land S_2(t') \le p_2 \land ... \land S_k(t') \le p_k$. Therefore, for any $(p_1, p_2, ..., p_k) \in \mathbb{R}^k$ and every i = 1, 2, ..., k, we have $S_i(t) \le p_i \rightarrow S_i(t') \le p_i$.

Proof of Theorem 1: The Checkpoint algorithm correctly solves the EQPE problem, i.e., if *argmax* $O(p_1, p_2, p_3, p_4, p_5)$, where O is the objective function of the EQPE problem.

The time complexity is $O(kN\log N)$, where k is the number of time series and N is the size of the learning data set.

Proof: To prove the correctness of the algorithm if it is sufficient to show **Claim 2**: The Non-Dominance test in STEP 2 of the Checkpoint Algorithm is satisfied for the time point t if and only if there does not exist t' that dominates t, where $0 \le t' \le t$.

We prove it by induction on *t*, where $1 \le t \le N$. For t = 1, $T_{kd} = \emptyset$ and t = 1 is not dominated; therefore, the "if and only if" condition holds. Assuming the correctness for 1, 2, ..., *t*-1; it follows the STEP 2 of the algorithm that T_{kd} at point t contains all non-dominated time points *t*', where $t' \le t - 1$.

If Direction:

The IF part of Claim 2 is straightforward since if t is not dominated by an earlier time point t', such point cannot appear on the T_{kd} tree; therefore, the Non-Dominance Test must be satisfied by Claim 1.

Only If Direction:

For the ONLY IF part of the Claim 2, assume that the Non-Dominance test in STEP 2 of the algorithm is satisfied. Then there does not exist the time point t' on T_{kd} for which $(S_1(t'), S_2(t'), ..., S_k(t'))$ $\in [S_1(t), \infty) \ge [S_2(t), \infty) \ge \dots \ge [S_k(t), \infty)$, where $0 \le t'$ < t. Assume that T_{kd} at time t contains the time points $t_{1_i} < t_{2_i} < \dots < t_{m_i}$ and assume, by contradiction, that there exists t' that dominates t, t'> t, where $0 \le t' < t$. Clearly, t' is not one of $t_{1_i} < t_{2_i} < \cdots < t_{m_i}$ because they do not dominate t by the induction hypothesis. Because t' was not added to the T_{kd} tree and the induction hypothesis, $t_{i_i} > t'$ for some j = 1, 2, ..., m. From the contradiction assumption t' > t and the transitivity of >, it follows that $t_{j_i} > t$. Thus, by Claim 1, $S_1(t_{j_i}) \le S_1(t) \land S_2(t_{j_i}) \le S_2(t) \land \dots \land S_k(t_{j_i}) \le$ $S_k(t)$ which contradicts the fact that the Nondominance test in STEP 2 was satisfied for t. This completes the proof of Claim 2 and of the correctness of the algorithm.

Time Complexity: The algorithm performs N iterations in STEP 2, spending time $O(k\log N)$ using the T_{kd} algorithm (Bentley, 1975 & 1979) for the T_{kd} range query in Non-Dominance Test. Thus the overall complexity is $O(kN\log N)$.
