Abstract: The first course on programming is fundamental in the Facultat d’Informàtica de Barcelona. After a major redesign of the Programming-1 course in 2006 to give it a more practical flavor, an increasing number of measures have been undertaken over the years to try to increase its pass rate while maintaining a fixed quality level. These measures, that can be roughly summarized as an important increase in assessment, imply an increase in the workload of both students and instructors that does not always correspond to the increase of pass rate they provide. In this paper, and within the context of this course, we analyze quantitatively the amount of work required from faculty to implement the series of measures and we conclude that, within this course, continuous assessment is expensive and has reached its limit.

1 INTRODUCTION

The Programming-1 course at the Facultat d’Informàtica de Barcelona of the Universitat Politècnica de Catalunya involves about 450 first-year students, about 15 faculty members and two coordinators per semester. In September 2006, the course’s coordinators redesigned the course adopting a “learn-by-doing” approach (Arrow, 1962): from the very beginning, students were expected to solve a strategically and carefully organized collection of programming problems. An integral part of the course was an online programming judge that automatically verifies in real time whether student solutions are correct (Petit et al., 2012). Students are organized into groups that weekly have 3 hours of theory lectures as well as 3 hours of practical lessons in a computing laboratory. An account of the first two years of this experience is given in (Giménez et al., 2009), where it is shown that, unfortunately, a high number of students failed to pass the course. Indeed, the data collected on the online judge showed that the effort that most students dedicated to the course was far from the required workload (7.5 ECTS²). In fact, the data compiled by the system and the observations made by instructors also show that, in general, most students did not even invest in the course the time needed for the theory lectures and the laboratory sessions.

As lecturers in a technical university we are deeply engaged in the development of a learning society. However there is a big gap between general theories (Arrow, 1962; Solow, 1997; Stiglitz and Greenwald, 2014) and our everyday lecturing task. Concerned and committed to the challenge of helping students to achieve the practice and knowledge required to attain a passing mark, the Programming-1 academic staff have been introducing, over time, a series of measures with the intention of motivate students to work harder, more autonomously and more continuously while maintaining the general goals, level and approach of the course. As a consequence, the course has suffered several amendments, which, overall accounts for an important increase of continuous assessment of students at the expense of a parallel increase of the workload of the faculty.

The time devoted to teaching is a limited resource and it should be optimized with no detriment of its quality. To do so, a fundamental issue is to estimate the cost-benefit of the different faculty tasks. Such information would help to the assessment of the taken measures in terms of productivity (or effectiveness). This paper is a proposal on this direction and can pro-

²European Credit Transfer and Accumulation System (ECTS) is a standard for comparing the study attainment of higher education across the European Union. One ECTS credit corresponds to 25 hours of student work.
provide a starting point for fruitful discussions.

Specifically, we perform a cost–benefit analysis that determines the impact of those continuous assessment’s measures by contrasting the pass rate of the students with the workload of the instructors. To do so, we describe the series of measures that have been applied to the editions of the course from its inception and we present some data about their implementation. We propose a simple way to interpret them under economic terms by means of productivity and marginal gain notions (Varian, 2005).

At first, our methodology consists in recognizing which changes have been applied to the course since its kick-off. This results in a series of measures labeled with timestamps that serve as the time basis of our study. The analysis of the temporal evolution of evaluative activities for a course is a well established subject (Martín-Carrasco et al., 2014). Following a long tradition in education analysis (Bowles, 1970; Hanushek, 2008), we use the rate of students passing the course as our primary measure of production. Following a well-recognized evaluative activities for a course is a well-established subject (Martín-Carrasco et al., 2014). Following a long tradition in education analysis (Bowles, 1970; Hanushek, 2008), we use the rate of students passing the course as our primary measure of production. Specifically, we use the following magnitudes:

- \( N_t \) denotes the total number of students at time \( t \),
- \( P_t \) denotes the number of students passing the course at time \( t \), therefore
- \( 100P_t/N_t \) corresponds to the pass rate at time \( t \) and,
- \( W_t \) denotes the total number of working hours required from the faculty members to teach the course at time \( t \).

It is clear that our model and our data are limited and do not take into account several pedagogical, psychological and sociological aspects that affect the behavior of both students and faculty members. Nevertheless, we think that it can provide insights in the way this massive course has evolved as well as tools for future directions.

According to the results reported in this paper, we can provide criteria to assess the benefit of each of the introduced measures. We can observe that the benefit of incrementing the load of continuous assessment reaches soon a limit, regarding the pass rate of the students and the instructors’ workload.

The forthcoming sections are organized as follows. First, in Section 2, we give an overview of the context and original design of the course, as well as a description of the different evaluative activities proposed over the latter years. Then, we describe the impact of those measures on the pass rate of the students in Section 3. The total workload induced by this course is described and estimated in Section 4. An analysis in economical terms is carried out in Section 5. Finally, in Section 6, we present our concluding remarks.

2 THE COURSE: CONTEXT, DESIGN AND EVOLUTION

Context. In the Spanish educational system, the admission to Universities (in terms of number of vacancies, threshold qualification, etc.) is established by a public government office which is independent of universities. After concluding their secondary studies, students must do a multi-subject general test in order to be able to apply for a university vacancy. Those tests are valid countrywide. Thus, in general, first-year students are not previously filtered by any specific admission exam designed by Universities. In order to compensate that lack of specific filtering, the first year in most of the degrees somehow becomes a selective procedure. That happens also at the Facultat d’Informàtica de Barcelona where, at the end of the first year, many of the approx. 450 incoming students will drop out. The current selection criteria at the Facultat d’Informàtica de Barcelona is that all four subjects composing the first year of the degree must be successfully passed in at most four consecutive semesters.

Table 1 shows, for the academic year 2006-2007, the percentage of students passing the first four semesters at their first try in our school. We are not entering in the debate of what is an acceptable pass rate. However, there is a general agreement that the percentage for Programming-1 was too low and should be improved.

With respect to Programming-1, by 2006 there was also a big consensus on the fact that, independently of their grades, most students did not master the programming skills needed for subsequent courses. Consequently, the Programming-1 course was completely redesigned in September 2006. This was done under the agreement that the level of required programming skills were correctly designed and should not be changed in the coming years. In the following subsection we give a short overview of the new course (full details can be found in (Giménez et al., 2009)).

Design. The main goal of the new Programming-1 course was to ensure that students would learn and master basic practical programming skills. In order to achieve this goal, the course was organized around the notion of “programming problems”, that is, small programming tasks, specified in terms of valid inputs and desired outputs, for which students must write
a small, correct and efficient C++ program performing the required tasks. During the course, students would solve as many programming problems as possible among a collection containing more than 300 problems. The collection was conveniently organized by topic and difficulty. Some of these problems were expected to be solved individually during the laboratory sessions with the help of an instructor; some others were expected to be solved without the instructor’s immediate support. Theory sessions were used, as usual, to introduce the techniques and tools required to solve the problems. In the exams, students were asked to solve programming problems with a difficulty similar to those in the collection. Those exams took place in the laboratory room where students used to work every week.

In order to apply this methodology, an online educational programming judge was developed (Petit et al., 2012). Online programming judges are web systems that store a repository of problems with the facility to check whether a candidate solution is correct. The judge executes the submitted program on a set of public and private test cases, and matches the obtained outputs with the expected ones. Online judges originated in programming contests such as the UVa Online Judge (Revilla et al., 2008), and have widely been adapted to educative settings (Ihan-tola et al., 2010; Verdú et al., 2012; Tonin et al., 2012). In particular, the judge of Programming-1 has evolved into www.jutge.org, an open access virtual learning environment for computer programming (Petit et al., 2012).

The judge was an inflection point for our programming courses. Indeed, this kind of public good offers advantages to the students since it is a tool to freely work and study as it may be used 24/7. Also, it is an invaluable help to instructors. Allowing to track easily the work and evolution of their students and for the assessment of exams.

In particular, the judge was also used during the exams, where it was compulsory to submit a correct solution in order to be evaluated. After the exam, only the correct solutions were additionally checked by human instructors, mainly to grade their adequacy to general quality criteria. The aim of this strict rule was to force students to put a lot of effort to practice on their own. However, our students perceived it as really unfair.

The results of introducing this methodology of teaching and learning to program were not as successful as expected at the very beginning. As a consequence, several measures were taken with the intention of turn the situation around. In what follows, we describe those measures and comment on how they affected the evolution of the course.

Evolution. In order to try to improve its learnability, and therefore its pass rate, a series of gradual modifications were applied to the course as initially conceived. As it will be seen in the next section, none of these measures was able to boost the rate of success on its own, a fact that resulted in their continued application over the years.

Specifically, this is the list of the main measures applied to the course organization since its kick-off, dividing the total time span into eight periods \(t_0, \ldots, t_7\):

- \(t_0\) Kick-off (2006-2007): The first edition of this course started with 3 hours of theory lectures addressed to groups of 60 students and 3 hours of practical (laboratory) sessions addressed to groups of 20 students. There were two exams (a mid-term exam and a final exam) consisting of two practical problems each. The exams took place at the same rooms where students were used to work every week on their practical lessons. The students were asked to solve the problems, to implement their solutions and to submit their programs to the online judge. Each solution to a problem could be submitted more than once. Each submission gets a verdict from the online judge in a few seconds. Only those programs accepted by the Judge (labeled with a green light, see Figure 1) were then graded by the instructors. The rest (i.e., those labeled with a red light) were given the lowest mark: a zero, in the Spanish system.

- \(t_1\) Introduction of quizzes (2007-2008): In order to encourage students’ continuous work, four addi-

Figure 1: Jutge.org with two of its verdict icons: The green light icon for submissions that pass all the test cases of a problem, and the red light icon marking submissions that fail some test cases.

### Table 1: For each subject in the academic year 2006-2007: #Stu is the total number of students; %Enr is the percentage of students who pass; and %Exa is the percentage of students who pass among those who took the final exam.

</table>
tional practical exams were distributed along the semester. Those exams consisted of an exercise of the same format and complexity as those solved in the practical sessions, and thus simpler than the problems included in the mid-term and final exam. The goal of this action was two-fold: first, to help students to get used to work under the same scenario, of the final exam, and second, to encourage them to work hard and get good marks. They could obtain up to a 10% of the final qualification by working continuously and succeeding in those exams.

\( t_2 \) Grading red lights (2008-2009): Several lecturers and the majority of students considered that the fact of grading only those solutions labeled green by the online judge was unfair. Therefore, the Facultat d’Informàtica de Barcelona urged the coordinators of the course to remove this rule, and to manually grade all the solutions (including the incorrect ones, the ones that did not succeed to get a green light by the online judge).

\( t_3 \) Written final exam (2009-2010): There was also the feeling among a few lecturers and some students that the fact that exams were only practical and ran in front of the computer, was also a cause of failure. In order to neutralize that opinion and minimize the effects of that situation, the hands-on practical final exam was replaced by a final written (traditional) exam.

\( t_4 \) New degree (2010-2011): In September 2010 the Facultat d’Informàtica de Barcelona introduced a new curriculum for the Degree of Computer Science to comply with the new law of the European Union regarding graduate studies. This new curriculum is the one that the Programming-1 course currently follows. The most relevant changes were: (a) that the theory lectures were reduced from 3 to 2 hours, and (b) that practical exercises became mid-term exams with a greater weight on the final mark.

\( t_5 \) Lists of problems to hand-in (2011-2012): To enforce continuous work again, several lists of mandatory practical exercises for each topic of the course were introduced. Those lists were composed by the standard exercises which were already included in the set of problems of practical sessions. Therefore, the students had the possibility to solve them before the exam.

In order to be accepted to mid-term exams, students must properly solve and submit (via the online judge) around 70% of the exercises of those lists. The mid-term exams’ problems were taken from those lists.

\( t_6 \) Re-evaluation course (2012-2013): As another effort to increase the rate of success, the Facultat d’Informàtica de Barcelona introduced the concept of a remedial exam for students whose grade was not good enough but not bad enough. Once the usual course is finished, these students could apply for remedial lectures that consisted in intensive daily sessions of 2 hours each, during 6 consecutive days. Attendance to the lectures is mandatory. The re-evaluation course gives the students who are very close to pass the course, the right to a further examination. As in the normal course, that right is also conditioned to solving 70% of the problems of some proposed lists. If a student does not pass the remedial exam, the original qualification of the course is kept. Otherwise, the minimal mark that allows to pass (a 5, in the Spanish system) is awarded. No higher marks can be obtained.

\( t_7 \) Quizzes not from the lists (2013-2014): In order to lead the students towards a more creative learning, the mid-term exams are now composed by new problems instead of by problems coming from the lists. Those problems are unknown to the students by the time of the exam.

3 PASS RATE

Taking into account the history of the course detailed in the previous section, we now turn our attention to the evolution of the pass rate (or rate of success) as a function of the measures taken over time.

Table 2 shows, by timestamp, the number of enrolled students and the number of students that pass the course. Figure 2 shows the pass rate from the timestamps \( t_0 \) to \( t_7 \). Notice that \( t_0 \) is labeled as 2007 but the data corresponds to the course 2006-2007. Similarly for other timestamps. One can see that the proportion of students who pass the course in a first attempt started at around 20% and is now close to 40%. More specifically, it is also shown that:

- The introduction of quizzes at \( t_1 \) had almost no effect in the percentage of students who finished the course successfully.
- Grading red lights at \( t_2 \) had almost no effect on increasing the success of students (but, at least, it removed the feeling of unfairness).
- The introduction of a written final exam at \( t_3 \) modestly improved the percentage of success by a 3%.
- The adaptation to the new degree at \( t_4 \) had some effect, since this last modification boost the per-

4 WORKLOAD

Our goal in this section is to estimate the workload of the course, \( W_t \), \( t \in \{ t_0 , ... , t_7 \} \), in each of its stages, measured as the total number of working hours invested by faculty members.

Computing \( W_t \) is difficult because every new edition of the course involves slightly different tasks to be performed by faculty members with different profiles, dedications and efficiencies. Moreover, the faculty members involved in the course also change from semester to semester. Additionally, the perception of each faculty member about the time invested in each task is also different.

We have approximated \( W_t \) by decomposing it into several tasks and conducting a survey among the current instructors of the course to get their cost (in hours) estimates, for each of the tasks. Therefore, \( W_t \) is conformed by the number of working hours required to:

- \( T_t \): lecture theory.
- \( L_t \): supervise practical lectures.
- \( E_t \): design, test and prepare exams.
- \( G_t \): mark exams.
- \( V_t \): supervise exams.
- \( C_t \): coordinate the course.
- \( S_t \): maintain software.

To a greater or lesser extent, all these quantities (except \( S_t \)) are dependent on the number of students. We have not included here the working hours required for the initial design of the course and of the design and implementation of the online judge.

The value used here for estimating each of these measures is the average over 14 answers received in survey carried out at the end of the last semester (fall semester of the course 2014-2015). Since we did not have similar information from previous editions of the course (and it would have been almost impossible to obtain it), we extrapolated the results to past editions taking into account the way in which each applied amendment impacted the workload of each task. The technicalities for the calculation of the values of each task are given in Appendix A, and these values are shown in Table 3.
Table 3: Timestamp \(t\), workload (in hours) of the tasks of the course.

</table>

Figure 3: Workload (in hours) of each task of the course by year (timestamp). A graphical representation of the first eight columns in Table 3.

Figure 3 shows the evolution over time of the workload of each of the tasks. One can see that the most significant contributions to the total cost \(W_t\) at each timestamp are practical lectures and theory lectures. In spite of that, the faculty members have the impression that the same does not apply to students. The tendency among many students as the course advances is not to attend lectures.

One can also see that all the tasks—except \(V_t\) and \(G_t\)—are almost constant over time. Both \(V_t\) and \(G_t\) increase from \(t_0\) to \(t_7\) and are the principal reason why \(W_t\) also increases. Indeed, this behavior is as expected because the measures introduced along the years are mostly evaluative ones (i.e., directly or indirectly in the form of exams) and then it is natural that they mostly impact the tasks involved in designing, supervising and assessing exams.

Having the total workload hours \(W_t\) required for the course at every \(t\), we can calculate the faculty workload per student at timestamp \(t\) as

\[ W_t^s = \frac{W_t}{N_t} \]

This measure indicates how many of the working hours of the faculty members are dedicated to each student. In other words, it indicates what is the cost of every student in terms of faculty working hours. Figure 4 shows the evolution of this cost over time. As the plot shows, the cost per student increased by an hour from \(t_0\) to \(t_7\). As we said before, this extra hour exclusively corresponds to the increase in grading and supervising (\(G_t\) and \(V_t\), respectively). Figure 4 shows that almost all the increment on the cost per student appears at \(t_2\), together with the measure of grading also the programs that obtained a red-light verdict by the online judge. In spite of that effort, we previously shown that the \(t_2\) amendment did not have much influence on the pass rate.

### 5 ANALYSIS

In this section we go deeper into the analysis of the pass rate and the workload by relating them through economic concepts.

On the surface, one can think that the whole evolution of the course (by means of the measures taken) is a great success since the whole workload \(W_t\) incremented by a modest 13% while duplicating the rate of success of the students. However, the measures taken did not affect the whole workload but only \(G_t\) and \(V_t\).
that were (at least) triplicated. Therefore, the duplication of the rate of success does not seem to justify the triplication of $G_t + V_t$.

In order to get more insight on how each measure affects the pass rate, in the following we conduct a cost-benefit analysis relating workload and pass rate.

Economists define productivity or effectiveness as the ratio of outputs to inputs used in the production process (Varian, 2005). In our case, being very coarse and with all the safeguards and warnings required, one can see the number of students that succeed the course as the output and the total workload as the input. Therefore we talk about the course productivity $\Pi_t$ as the ratio of these two quantities over time. This is,

$$\Pi_t = P_t / W_t,$$

Figure 5 shows the behavior of $\Pi_t$ from $t_0$ to $t_7$. Looking at the plot we can observe that $\Pi_t$ has the typical S-curve shape in economic terms (Varian, 2005). The interpretation that it is generally given to this kind of curve is that if one reaches the inflection point (as it seems to be our case, although we have few observations after this inflection point) there is no sense to continue increasing the input (i.e., the workload of the course, in our case) because this increment has no impact on the output. In fact, it is negative.

Specifically the curve of $\Pi_t$ has three sections that are noteworthy:

1. The first one is from $t_1$ to $t_2$ in which $\Pi_t$ decreases due —as we already mentioned— to the grading of exam problems labeled with a red light verdict by the online judge.

2. The second one is from $t_2$ to $t_5$ where it increases. During this period we can read from the curve that the course was being productive in the sense that the amendments applied were being effective as was the increase of the workload.

3. The last period corresponds to $t_5$ to $t_7$ in which $\Pi_t$ drastically decreases. In this period the workload increased but the number of students that passed the course decreased. This is because the midterm practical exams are currently composed by new problems that are not known in advance by students.

We consider now more closely the impact of the different measures over time. To capture the variation of work among periods we define

$$\Delta W_t = W_t / N_t - W_{t-1} / N_{t-1}$$

and for the variation of students that pass the course we define

$$\Delta P_t = P_t / N_t - P_{t-1} / N_{t-1}.$$

We compare both of them by the rate

$$\Delta = \Delta W_t / \Delta P_t.$$

Abusing again of economics terminology, we call this rate the marginal gain at time $t$ of the undertaken measure (Varian, 2005).

Let us consider the following five general cases:

a) Case $\Delta W_t > 0$ and $\Delta P_t < 0$. Increasing the workload while decreasing the percentage of successful students corresponds to a very negative undertaken measure. It seems definitely a situation to avoid.

b) Case $\Delta W_t < 0$ and $\Delta P_t < 0$ can be considered in general as a negative option; of course one wants to decrease $\Delta W_t$ but not with the consequence of decreasing also $\Delta P_t$. However, if $|\Delta W_t| > |\Delta P_t|$ the undertaken measure deserves to be carefully analyzed. It might be the case that a small decrease in $\Delta P_t$ is justified if it implies a huge decrease of the workload.

c) Case $\Delta W_t \geq 0$ and $\Delta P_t \geq 0$ and $\Delta W_t \gg \Delta P_t$. This corresponds to a big increase of work for a small increase in the number of passing students, which is in general a situation to avoid.

---

**Figure 4:** Hours of faculty work per student by year (timesamp). A graphical representation of the last column in Table 3.

**Figure 5:** Productivity by year (timestamp).
d) Case $\Delta W_t \geq 0$ and $\Delta P_t \geq 0$ and $\Delta P_t \gg \Delta W_t$. This is a positive case, a small increase in the quantity of work produces a big improvement.

e) Case $\Delta W_t < 0$ and $\Delta P_t > 0$. This is in general an outstanding measure. The larger the distance between $\Delta W_t$ and $\Delta P_t$, the better the measure.

It is worth observing that the cases where $\Delta_t$ is really unbalanced deserve special attention. Such cases reflect an important disagreement between the effort (measured by $\Delta W_t$) and the results (measured by $\Delta P_t$).

Let us now interpret the amendments taken in this course in terms of the cases above. Table 4 shows the values of $\Delta P_t$, $\Delta W_t$ and $\Delta_t$ over time.

$t_5$ Lists of problems to hand-in (2011-2012): This seems to be an outstanding amendment. It falls under Case e). However one has to be prudent with such kind of amendments. There is no doubt that it increased the rate of success while decreasing the workload, but the contents of mid-term exams were previously known by students. At the end, that might be a drawback because of the indirect use of mechanical learning, which is a risky practice. As C. P. Snow strongly stated:

“It was an examination in which the questions were usually of considerable mechanical difficulty, but unfortunately did not give the opportunity for the candidate to show mathematical imagination or insight or any quality that a creative mathematician needs.” (See foreword of (Hardy, 1940).)

$t_6$ Re-evaluation (2012-2013): This can be considered a positive amendment despite being very expensive. It falls under Case d).

$t_7$ Quizzes not from the lists (2013-2014): This amendment falls under Case a). It seems to be a situation to avoid if one looks only into the numbers. However, when related to the situation at $t_5$, it seems to confirm our perception that the students are learning in a more mechanical way.

6 CONCLUSIONS

In this paper we have described the series of measures taken to increase the pass rate of the Programming-1 course since its inception. The successive introduction of these reported measures increased the weight of continuous assessment as a way to incentive students work.

However, it appears that despite applying all these measures, the rate of success of this massive course has not increased as much as expected, while in fact, all this increase of continuous assessment produced a significant increase of the faculty workload.

In order to obtain a quantitative assessment of the impact of each measure over both workload and pass rate we have introduced two functions: productivity
and marginal gain. These functions provide a way to rank the adopted measures as negative or positive. Our findings are valuable for the design of future strategies for this and similar courses.

The analysis tools reported on this study provide a way to analyze the effectiveness of new measures. According with their corresponding cost-benefit analysis, the measure can be maintained, tuned or withdrawn, under the general hypothesis that the current content of the course as well as the proficiency levels achieved by students who passed the course should not be changed.

In particular, for some of the adopted measures, it becomes clear that the amount of invested resources (faculty workload) did not justify their impact in the pass rate. For instance, the substantial overhead of grading red lights had almost no impact on passing rate. Other measures did have a positive impact without increasing the workload like the weights given to the different exams. Moreover, as all the introduced measures involve continuous assessment, our study shows that the corresponding workload has reached its limit.

Some pedagogical strategies around the use of the online Judge as an automated aid to motivate, help and evaluate students that are used in this course have been successfully used also in other courses (such as Programming-2, Data structures and algorithms, Algorithms, Functional programming, among others). It could be interesting to extend this kind of analysis to those courses.

We are aware that the scope of our study could be extended. We have focused uniquely on the passing rate but a finer analysis taking into account students marks and motivation might bring more insights in the effectiveness of every measure.

A TECHNICAL DETAILS

In this appendix we calculate the amount of working hours per task at each stage of our course based on the 14 answers that we obtained by surveying current instructors and extrapolating these values to previous timestamps. Note that most measures, once taken, remain in force, thus the workloads involved are accumulated.

$\text{t}_0$ Kick-off (2006–2007): The course started with two kind of lectures, theory and practical, of 3 hours per week each. Theory lectures were given to groups of 60 students, and the survey says that in average it takes 1.5 hours to prepare one hour of theory lectures. This results in a total of 2.5 hours of work (preparation + lecturing). Since the course is 15 weeks long, we have:
Grading red lights

In two turns. Considering that the time required to grade the small exam of one student was 1.5 hours and that the preparation of each small exam was 1 hour, we have that $T_0 = 2 \times 3 \times 15 \times \frac{N_t}{60}$.

There were two exams of 2 problems each. There were 2 turns of exams (morning and afternoon), all the students that have morning classes are examined with the same exam which is different from the exam of the afternoon students. So 4 problems should be prepared (2 per turn). Since each exam lasted for 2 hours and the students were distributed in laboratory rooms with 20 computers we have that $V_0 = 2 \times 2 \times \frac{N_t}{20}$. We estimate that the preparation of each problem takes in average 3 hours of work (this include writing the statement, implementing the solution and designing the tests that the system requires to judge the submissions). Therefore, $T_0 = 24$. Only the solutions of students that obtained a green light for a problem were graded by hand, and this was, approximately, a third of the students, so $G_0 = 2 \times 2 \times 0.2 \times \frac{N_t}{20}$ hours, considering that grading one problem takes 12 minutes.

The coordination of the whole course has a fixed cost $k$ plus a cost that depends on the number of students of each course. We estimate this last amount in one half hour per group of 10 students, then $C_0 = k + 0.5 \times \frac{N_t}{10}$. Finally, we are estimating that the software maintenance takes 4 hours a day yielding to $S_0 = 4 \times 5 \times 15$ per course.

t1 Introduction of quizzes (2007–2008): In this period 4 small mid-term exams were introduced in addition to the two original exams and they were applied also in two turns. Considering that the time required to prepare each small exam was 1.5 hours and that the time required to grade the small exam of one student was 6 minutes, this measure increased $E_0$ and $G_0$ to $E_t = E_0 + 4 \times 2 \times 1.5$ and $G_t = 4 \times 0.3 \times \frac{N_t}{20}$. The workload of all the other tasks remained the same.

t2 Grading red lights (2008–2009): When all the submissions (and not only the green labeled ones) have to be graded $G_t$ was triplicated. $G_t = 4 \times 0.3 \times N_t$.

t3 Written final exam (2009–2010): At this point the final exam was changed to be a written exam of 3 problems. The exam was organized in only one turn applied to all the students (same exam for all students). The time to prepare a problem for a written exam is estimated in 2 hours (1 hour less than the time of a practical exam). Therefore $E_t = E_0 - 2 \times 2 \times 3 + 3 \times 2$. The written exam lasts for 3 hours. Since larger rooms (with place for 60 students) can be used for a written exam, $V_t$ decreased to $V_t = 2 \times \frac{N_t}{20} + 3 \frac{N_t}{20}$.

t4 New degree (2010–2011): With the new degree the hours of theory lectures per week decrease from 3 to 2 per group yielding $T_0 = 2.5 \times 2 \times 15 \times \frac{N_t}{60}$. The evaluation system also changed. The big mid term exam disappeared. The four small mid term exams became formal exams of one problem each. Thus, $E_t = 4 \times 3 \times 2 + 2 \times 3$. The first 3 mid term practical exams lasts 1.5 hours each while the last one for 2.5 hours. The final exam still lasts 3 hours, thus $V_t = (3 \times 2 \times 1.5 + 2 \times 2.5) \frac{N_t}{20} + 3 \frac{N_t}{20}$.

t5 Lists of problems to hand-in (2011–2012): A list of problems per exam to be delivered by the students before the exam was introduced. The problems of the exams were chosen from the problems of the list. The preparation of each laboratory problem decreased to 1.5 hours. Hence $E_t = 4 \times 2 \times 1.5 + 3 \times 2 = 18$. Finally, the preparation of the lists increase $G_t$ by 10 hours, so that $C_t = k + 10 + 0.5 \frac{N_t}{10}$.

t6 Re-evaluation (2012-2013): This measure added 3 hours to $E_t$, 20 hours to $T_t$, 60 hours to $E_t$, 15 hours to $G_t$ and 3 hours to $V_t$.

t7 Quizzes not from the lists (2013-2014): This measure involved the creation of new problems for the mid-term practical exams, instead of taking them from the lists. This increased the time for preparing each problem from 1.5 to 3 hours. Thus $E_t = 4 \times 2 \times 3 + 3 \times 2 = 30$. 

$t_0$ hours =
$$\begin{align*}
&= (1 + 1.5) \times \frac{1h \text{ theory}}{\text{week} \times \text{group}} \times 15 \text{ week} \times \frac{N_t}{60} \\
&= 1.7 \times N_t
\end{align*}$$

where $N_t$ is the total number of enrolled students at time $t$. Proceeding similarly for practical sessions and considering that the size of the laboratory groups is of 20 students, and that the preparation of each hour of practical sessions takes 1 hour, we have that $L_0 = 2 \times 3 \times 15 \times \frac{N_t}{60}$.
