Keywords: Emotion Recognition, Violin, Music, Support Vector Regression, Fuzzy Logic.

Abstract: Emotion recognition of violin music is proposed based on strings music theory, where the emotional state of violin music is expressed by Affinity-Pleasure-Arousal emotion space. Besides the music features from audio processing, three features (i.e., left-hand feature, right-hand feature, and dynamics) with regard to both composition and performance of violin music, are extracted to improve the emotion recognition of violin music. To demonstrate the validity of this proposal, a dataset composing of 120 pieces of author-performed violin music with six primary emotion categories is established, by which the experimental results of emotion recognition using Support Vector Regression report overall recognition accuracy of 86.67%. The proposal could be an integral part for analyzing the communication atmosphere with background music, or be used by a music recommendation system for various occasions.

1 INTRODUCTION

Music not only helps people edify sentiment, but also plays an important role in psychotherapy such as elimination of stress and mood shift. Music emotion that is the feelings of audience inspired by music, therefore, has gradually recevied as much attention as human emotion. In music psychology, music is able to affect the feeling of listeners (Hargreaves, 1999). For example, when a person is sleepy, strong rhythm music could refresh him/her and decrease drowsiness; on the contrary, a lullaby helps children fall to sleep, all of which demonstrates the importance of music in generating emotions.

Recently, there are mainly two types of emotion recognition of audio signals, i.e., speech emotion recognition (Ayadi et al., 2011) and music emotion recognition (Kim, 2010), where the study of music emotion always focuses on extraction of features from audio processing such as intensity features, timbre features, rhythm features (Lu, et al., 2006). Another two important emotion-related components – composition and performance of music, however, are seldom used for music emotion recognition, and both of them are associated with music theory.

Music is a broad concept that includes different types, e.g., classical music, folk music, rock music, opera music, and others. Music can be performed by various instruments all around the world, for example, violin, cello, piano, guitar, trumpet, flute, drum, and so on. A general model of music emotion, therefore, is not easy to create. Instead, study on emotion recognition of particular types of music or music performed by one kind of instrument should be taken into account.

Classical music is the most typical type of music worldwide, in which the elements of music such as melody, harmony, and rhythm are all well-balanced. Furthermore, it is an ideal object of study for emotion recognition because of its richness of emotions. To play the classical music, violin, a four-string instrument tuned in perfect fifths, is the best

ISBN: 978-989-8565-21-1

choice since it is recognized as the melodic backbone of most classical music (Starks, 2012) and plays a leading role in emotion expression.

Emotion recognition of violin music based on strings music theory is proposed to realize casual communication between humans and robots in Mascot Robot System (MRS). In the MRS, both speech emotion recognition and music emotion recognition are implemented, using Affinity-Arousal-Pleasure emotion space to describe the emotional states. In addition, for many-to-many communication, multiple emotional states including humans, robots, and background music are taken into consideration for analyzing communication atmosphere which is defined as Fuzzy Atmosfield (Liu et al., 2011).

In terms of the relationship between the characteristics of the violin music and the feelings of audiences, three features of violin music including left-hand feature based on "Just Intonation", right-hand feature based on metronome, and dynamics based feature are proposed, which are closely associated with the three attributes of emotion space, respectively. Inspired from this idea, three sets of features, namely, harmony, rhythm, and dynamics as the extension of the proposed features are extracted.

Six basic emotion categories, i.e., happiness, sadness, comfort, disgust, anxiety, and surprise are adopted for emotion representation of violin music. A dataset of 120 pieces of violin music played by the author is established for the experiment. Support Vector Regression (SVR) is employed for training the emotion model with 60 pieces of violin music, and other 60 pieces are used for testing. The experimental results confirm the validity and availability of the proposal.

In 2, a brief overview of the Mascot Robot System is given. Emotion recognition of violin music based on strings music theory and Support Vector Regression is proposed in 3. In 4, experiments on emotion recognition of violin music and the application to background music selection for home party scenarios are presented.

2 MASCOT ROBOT SYSTEM

Mascot Robot System is an information presentation system within a networked robotic environment (Hirota and Dong, 2008), where robots facilitate a smooth and harmonious communication atmosphere with humans.

2.1 Framework of Mascot Robot System

The MRS has been composed of four fixed eye robots and one mobile eye robot (each eye robot equipped with speech recognition module (SRM), emotion synthesis module, and emotion recognition module), an information recommendation server, and a system server that is responsible for overall management, as shown in Fig. 1.

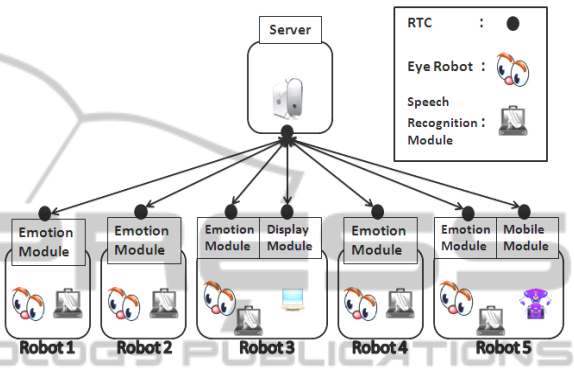

Figure 1: Framework of Mascot Robot System.

Using the emotion synthesis module, eye robots are able to express emotions based on the mechanisms of the human eye. Robot Technology middleware (RT Middleware) is used to connect among the system's components. With RT middleware, each robot can be viewed as a networked component and the whole system can be managed from the view point of service level (Yamazaki et al., 2010).

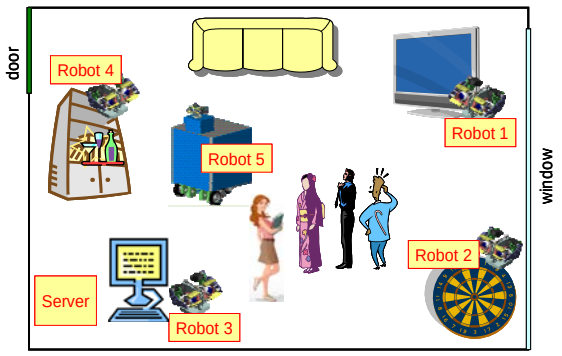

Figure 2: Household environment for human-robot communication.

Fig. 2 shows a household environment that is created for testing the MRS, where four fixed eye robots are placed on the TV, a dart game machine, an information terminal, and a mini-bar. The mobile eye robot accompanies and assists the users with

emotion expression by eye movement and voice communication.

2.2 Fuzzy Atmosfield for Analyzing Communication Atmosphere

For many-to-many communication, only emotion analysis is not enough for atmosphere understanding. Fuzzy Atmosfield (FA), therefore, is used to describe mood states among communicators being generated from not only the verbal and non-verbal information of speakers, but also background music or noise (Liu et al., 2011).

Besides the emotional states of individuals in the communication, environmental factors such as music are essential factors for the FA in a real life environment. As an independent emotional object, the emotional state of background music is defined as *M* in the function of the FA (Liu et al., 2011),

$$FA(t) = \begin{cases} f(E_1(t), \cdots, E_n(t), M(t)), & t = 1 \\ (1-\lambda)FA(t-1)\cdot\gamma + \lambda f(E_1(t), \cdots, & \\ E_n(t), M(t)), & t > 1 \end{cases} \quad (1)$$

where *FA* is the atmosphere state of the Fuzzy Atmosfield; *f* is the function of emotional states of *E* and *M* at time *t*, using fuzzy logic and weighted average method; E_i is the emotional state of the *i*th individual, *i*=1, …, *n*; *M* is the emotional state of the background music; λ is the correlation factor, $0 \le \lambda \le 1$; and γ is a monotonically decreasing function. In the MRS, Affinity-Pleasure-Arousal emotion space is used for the emotion representation of humans, robots, and background music.

2.3 Affinity-Pleasure-Arousal Emotion Space

The Affinity-Pleasure-Arousal emotion space is used to illustrate the emotional state of violin music. By using this emotion space, it is not only possible to express fixed emotional states but also to take into account rapid variations in the emotional state due to time involving music performance (Yamazaki et al., 2008), as shown in Fig. 3.

The "Affinity" axis represents the degree of empathy, i.e., intimacy (positive affinity) and estrangement (negative affinity); the "Pleasure-Displeasure" axis means happiness (positive values) and sadness (negative values); and the "Arousal-Sleep" axis expresses excitement (positive values) and calm (negative values).

To compute the emotional states of violin music

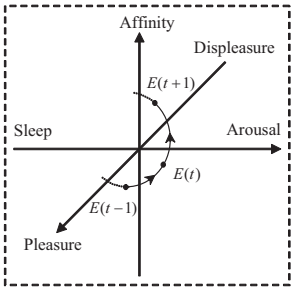

Figure 3: Affinity-Pleasure-Arousal emotion space.

in each axis of Affinity-Pleasure-Arousal emotion space, two steps should be implemented:

- The features of violin music that are related to each attributes (i.e., axis) of emotion space should be extracted and selected;
- Regression method should be used for training the relationship between attributes of emotion space and features of violin music.

3 EMOTION RECOGNITION OF VIOLIN MUSIC

3.1 Features of Violin Music based on Strings Music Theory

To define the features of violin music, left-handed fingering is taken as an example for emotion recognition of violin music in this paper.

Three basic elements of music, i.e., pitch, length, and strength, are highly associated with the attributes of the Affinity-Pleasure-Arousal emotion space. In violin music, the pitch varies when left hand fingers press the strings, for which the feature of pitch-related melody is named as left-hand feature; in addition, tempo-related feature is defined as right-hand feature since the music speed is correlated with right hand control of violin bow on the strings; and the feature based on dynamics is defined for representing the strength.

3.1.1 Left-hand Feature based on "Just Intonation"

The left-hand feature is defined according to the music theory of "Just Intonation" (Barbour, 2004). The violin has four strings which show the common G-D-A-E tuning in the case of open strings. Adjacent strings, in musicology, are defined as a pitch of "perfect fifth" in Fig. 4.

Figure 4: Perfect fifth of open strings.

The major third is obtained by adding another note in the middle of a perfect fifth. Diatonic scale can be obtained by adding a note in the middle of major third with the addition of pure intervals, as shown in Fig. 5.

Figure 5: Full scale of interval.

Semitone is defined as the smallest unit of Western music, and it is possible to determine the number of semitones in the interval between two notes. Interval, therefore, can be represented by the number of semitones and the ratio between frequencies of two notes in Table 1.

Table 1: Representation of interval.

Staff	Interval	Number of semitone	Ratio between frequencies
	unison	0	1:1
	minor second	1	16:17
	major second	2	8:9
	minor third	3	5:6
	major third	4	4:5
	perfect fourth	5	3:4
	perfect fifth	7	2:3
	minor sixth	8	5:8
	major sixth	9	3:5
	minor seventh	10	5:9
	major seventh	11	9:17
	octave	12	1:2

The ratio of f_1 to f_0 is expressed by

$$I_f = \log_2(\frac{f_1}{f_0}), \quad (2)$$

where $I_f \in [-1, 1]$. If I_f is positive, the melody changes in the shape of ascending, and the consonance of interval is increased towards a positive feeling; on the contrary, if it is negative, the melody changes in descending shape, and the consonance of interval is decreased towards a negative feeling.

Moreover, in musicology, if the interval with one more semitone and one less semitone than the "Major" or "Perfect" are defined as "augmented" and "diminished" (Zweifel, 2005); similarly, two more semitones and two less semitones are defined as "doubly augmented" and "doubly diminished".

For Western music, it is convenient to use the ratio between frequencies of two notes, whereas it is better to use the "consonant" interval for emotional analysis of music in musical psychology. In terms of this idea, the rules for the relationship between interval and consonance are formulated as illustrated in Table 2, where the consonance is classified into five categories including absolutely consonant, perfect consonant, relative consonant, imperfect consonant, and dissonant.

Table 2: Consonance of interval.

Interval	Consonance
unison, octave	absolutely consonant
perfect fourth, perfect fifth	perfect consonant
major third, minor third, major sixth, minor sixth	relative consonant
major second, minor second, major seventh, minor seventh	imperfect consonant
augmented or doubly augmented, diminished or doubly diminished	dissonant

The more consonant the interval is, the more pleasant the audience feels (Sethares, 1993), for which the consonance of interval is used to calculate the value of the "Pleasure-Displeasure" axis.

3.1.2 Right-hand Feature based on Metronome

Metronome is commonly used to maintain a consistent tempo with steady regular beats for play-

ing violin. It is a mechanical device that produces regular, metrical ticks (beats, clicks), which is settable in beats per minute (BPM). The BPM is a unit typically used as a measure of tempo in music. For example, ♩ = 72 BPM can be represented as 72 quarter notes in a minute. Fig. 6 shows a metronome with a pendulum-swing.

Figure 6: A photo of metronome from Wikipedia.

To specify the tempo, Grave, Largo, Adagio, Larghetto, Andante, Andantino, Moderato, Allegretto, Allegro, Vivace, and Presto (Brown, 1999) are used as shown in Table 3.

Table 3: Common tempo symbols for staff.

Tempo Sign	Meaning	BPM
Grave	slow and solemn	36-46
Largo	broadly	46-56
Adagio	slow and stately	56-63
Larghetto	rather broadly	63-72
Andante	at a walking pace	72-80
Andantino	slightly faster than andante	80-92
Moderato	moderately	92-108
Allegretto	moderately fast	108-132
Allegro	fast, quickly and bright	132-160
Vivace	lively and fast	160-184
Presto	very fast	184-208

Generally speaking, the tempo of music associates closely with perception of audiences (Juslin, 2000), in particular, a pair of emotional attributes – arousal and sleep. For example, fast tempo expresses arousing excitement but slow tempo inspires inactive mood. The BPM that is adopted as the right-hand feature, therefore, is used to determine the emotional states in the "Arousal-Sleep" axis.

3.1.3 Dynamics based Feature

The dynamics of Western music, not only refers to the volume, but also refers to the musical expression by the contrast of different performance methods. Table 4 shows the words indicating the change of dynamics (common dynamics signs), namely, *pp*, *p*, *mp*, *mf*, *f*, and *ff* (Nakamura, 1987).

Table 4: Common dynamics Symbols for staff.

Dynamics sign	Name	Meaning
pp	Pianissimo	very soft
p	Piano	soft
mp	Mezzo-Piano	moderately soft
mf	Mezzo-Forte	moderately strong
f	Forte	strong
ff	Fortissimo	very strong

As the intensity of music decreases, the distance perception is generated, while the degree of empathy is decreased. For example, when someone is depressed, he/she often feels lonely, tending to a negative mood. The features of dynamics (i.e., the strength of violin music performance), therefore, is used to estimate the "Affinity" in the emotion space.

3.2 Feature Extraction and Selection

Commonly used features (Kim et al., 2010 and Yang et al., 2008) for emotion recognition of audio signal are enumerated in Table 5, which can be summarized into six types, i.e., harmony, rhythm, dynamics, articulation, register, and timbre.

For the feature extraction, two free softwares PsySound (Cabrera, 1999), PRAAT (Boersma and Weenink, 2008), and a open-source Matlab toolbox *MIRtoolbox* (Lartillot and Toiviainen, 2007) are used.

In the light of the analysis of violin music theory in 3.1, three sets of features in Table 5, i.e., Harmony, Rhythm, and Dynamics, are employed to compute the values in "Pleasure-Displeasure", "Arousal-Sleep", and "Affinity" axes, respectively.

Table 5: Commonly used audio feature types.

Feature	Type
Roughness, Harmonic Change, Pitch Multiplicity, Dissonance, Key Clarity, Sharpness, Pure Tonal, Majorness	Harmony
Rhythm Strength, Regularity, Tempo, Beat Histograms	Rhythm
RMS Energy, Loudness, Sound Pressure Level, Volume, Spectral Centroid	Dynamics
Event Density, Attack Slope, Attack Time	Articulation
Chromagram, Chroma Centroid and Deviation	Register
MFCCs, Level, Sharpness, Spectral Shape, Spectral Contrast	Timbre

With the addition of the features in 3.1, nine features of Harmony (i.e., The Ratio between Frequencies of Two Notes, Roughness, Harmonic Change, Pitch Multiplicity, Dissonance, Key Clarity, Sharpness, Pure Tonal, and Majorness), five features of Rhythm (i.e., BPM, Rhythm Strength, Rhythm Regularity, Average Tempo, and The Ratio between Average Peak Strengths and Average Valley Strengths), and five features of Dynamics (i.e., RMS Energy, Loudness, Sound Pressure Level, Volume, and Spectral Centroid) are selected empirically for emotion recognition of violin music.

3.3 Emotion Recognition using Support Vector Regression

Emotion recognition of violin music using Support Vector Regression is proposed, where the regression analysis is utilized for analyzing the relationship between the value of each axis in the Affinity-Pleasure-Arousal emotion space and emotion-related features of violin music.

3.3.1 Overview of Emotion Recognition of Violin Music

In the emotion recognition process, the central task is to determine the emotional states of violin music based on the music features mentioned in 3.2 by using SVR. In addition, all the music features are normalized for the regression.

The framework of emotion recognition is shown as Fig. 7, mainly consisting of three steps:

- Training - SVR models are separately trained for each of the three axes in the emotion space, namely "Affinity", "Pleasure-Displeasure", and "Arousal-Sleep". The features are extracted from the violin music, and the target values for regression are obtained through questionnaire survey;
- Testing - For a coming piece of violin music, the emotional state is computed by using the trained SVR models;
- Emotion Classification - The distance between the positions of the tested piece of violin music and the state of each basic emotion in the emotion space is computed to determine the emotion category. The estimated states of the six basic emotions (i.e., happiness, sadness, disgust, comfort, surprise, and anxiety) are obtained by a questionnaire survey as well.

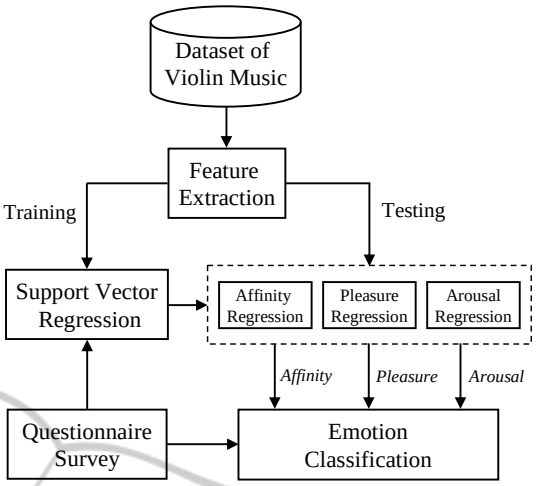

Figure 7: Framework of emotion recognition of violin music.

3.3.2 Support Vector Regression

Support Vector Regression is a powerful technique for regression based on Support Vector Machine (SVM) (Smola and Schölkopf, 2004), which shows outstanding performance in emotion recognition of speech (Grimm, Kroschel, and Narayanan, 2007) and music (Han et al., 2009) for quantitative analysis.

Suppose the training instances are described as follows,

$$\{(\mathbf{v}_1, y_1), \cdots, (\mathbf{v}_k, y_k)\} \subset \Re^n \times \Re, \quad (3)$$

where k is the number of training instances. The goal is to find a function $f^{(i)}$ which maps the n features of violin music $\mathbf{v}_k = (v_1, \ldots, v_n)^T \in \Re^n$ to the value of emotional state $y_k \in \Re$,

$$\hat{y}^{(i)} = f^{(i)}(\mathbf{v}). \quad (4)$$

Three SVR functions are created to estimate the values in the three axes of emotion space, i.e., $i \in \{Affinity, Pleasure, Arousal\}$.

The linear function f is described as follows,

$$f(\mathbf{v}) = \langle \mathbf{w}, \mathbf{v} \rangle + b, \ \mathbf{w} \in \Re^n, \ b \in \Re, \quad (5)$$

where $\mathbf{w}$ and b are the parameters of the hyperplane and $\langle \cdot, \cdot \rangle$ denotes the inner product.

The problem can be formulated as

$$\text{minimize } \frac{1}{2}\|w\|^2$$
$$\text{subject to } \begin{cases} y_m - \langle \mathbf{w}, \mathbf{v}_m \rangle - b \le \varepsilon \\ \langle \mathbf{w}, \mathbf{v}_m \rangle + b - y_m \le \varepsilon \end{cases}, \quad (6)$$

where $\varepsilon \geq 0$ denotes the maximum deviation between the actual and predictive target.

In order to eliminate the influence of noise and abnormal samples, the slack variables ξ_m and ξ_m^*, and a soft margin parameter *C* are introduced, which yields the following problem,

$$\text{minimize } \frac{1}{2}\|\mathbf{w}\|^2 + C\sum_{m=1}^{k}(\xi_m + \xi_m^*)$$
$$\text{subject to } \begin{cases} y_m - \langle \mathbf{w},\ \mathbf{v}_m \rangle - b \leq \varepsilon + \xi_m^* \\ \langle \mathbf{w},\ \mathbf{v}_m \rangle + b - y_m \leq \varepsilon + \xi_m \\ \xi_m,\ \xi_m^* \geq 0 \end{cases}. \quad (7)$$

The key idea to solve the optimization problem of Eq. (7) is to construct a Lagrange function, and then the above problem can be turned into a dual optimization problem. Finally, the regression function of $f(\mathbf{v})$ is given as follow,

$$f(\mathbf{v}) = \sum_{m=1}^{k}(\alpha_m^* - \alpha_m)K\langle \mathbf{v}_m, \mathbf{v}\rangle + b, \quad (8)$$

where α_m^*, α_m are Lagrange multipliers, and $0 \leq \alpha_m^*, \alpha_m \leq C$, $\alpha_m^* - \alpha_m \geq 0$. $K\langle \mathbf{v}_m, \mathbf{v}\rangle$ is the kernel function, where the Gaussian RBF kernel function is adopted to train the emotion model of violin music in Affinity-Pleasure-Arousal emotion space,

$$K(\mathbf{v}_m, \mathbf{v}) = \exp\left(-\frac{\|\mathbf{v}_m - \mathbf{v}\|^2}{2\delta^2}\right). \quad (9)$$

4 EXPERIMENTS ON EMOTION RECOGNITION OF VIOLIN MUSIC

4.1 Dataset of Violin Music

4.1.1 Emotion Category of Violin Music

There are mainly two kinds of methods for analyzing music emotion, namely, quantitative analysis and qualitative analysis, where the qualitative analysis can obtain the specific category of the music emotion.

Violin music emotion is actually the human emotion that is aroused or inspired by the violin music. Accordingly, different people will have their own emotion understanding of the same piece of melody, which means the evaluation of violin music emotion is somewhat subjective. In addition, it is difficult to perform detailed classification of music by nonprofessional people except musicians.

Among the acknowledged emotion categories, six basic emotions (Oatley and Johnson-Laird, 1987) including happiness, sadness, disgust, comfort, surprise, and anxiety are chosen for expressing the emotion of violin music.

To determine the coordinate of each emotion in the Affinity-Pleasure-Arousal emotion space, forty people from seven countries, aged 20 to 30 years, have participated in questionnaire survey with eighteen questions - How "Affinity"/"Pleasure"/ "Arousal" do you feel about each basic emotion? Seven answer options are given for each question, for example, to describe the "Pleasure", seven items that can be expediently chosen by the respondents are 1-Extremely Displeasure, 2-Very Displeasure, 3-Displeasure, 4-Medium, 5-Pleasure, 6-Very Pleasure, and 7-Extremely Pleasure. Each item is assigned with value for statistical analysis, i.e., 1 (-1), 2 (-0.66), 3 (-0.33), 4 (0), 5 (0.33), 6 (0.66), and 7 (1). The average coordinates from questionnaire survey are Happiness (0.58, 0.63, 0.54), Sadness (-0.47, -0.44, -0.33), Disgust (-0.34, -0.59, 0.27), Comfort (0.42, 0.17, -0.61), Surprise (0.27, 0.49, 0.58), and Anxiety (-0.14, -0.25, -0.18).

4.1.2 Violin Music Data Record

Violin music is performed by an author who has 25 years experience in playing violin, and it is recorded in a dataset which consists of 60 pieces of famous violin music selected from concerto, sonata, symphony, and sound tracks of movies and games, as enumerated in Table 6.

In general, a piece of violin music lasts minutes or tens of minutes. For the experiment, each piece is divided into shorter pieces, where each one lasts 15 seconds. Different movements in the same violin music may differ in melody and tempo, thus, emotionally touched clips of violin music are selected. Using these settings, 120 pieces of violin music in total are collected to form the dataset of the experiment. In this dataset, 60 pieces of the violin music are used for training, and other 60 pieces are for testing.

All the pieces of violin music in the dataset are recorded in a unified format. The A440 is adopted as the standard pitch; the standard tempo (Andante) of quarter note is set to 72 BPM. The sound tracks are recorded in 44100Hz, 16bit, and mono, and saved in WAV format.

Table 6: Samples of violin music with six emotions.

Emotion	Violin Music Piece	Composer
Happiness	Concerto No. 1 in E major, Op. 8, "La primavera" (Spring) 1st movement	Antonio Vivaldi
	Violin Concerto No. 4 in D major	Wolfgang Amadeus Mozart
	The Symphony No. 9 in D minor, 4th movement "Ode to Joy"	Ludwig van Beethoven
Sadness	Schindler's List	John Williams
	Castle in the Sky	Joe Hisaishi
	Zigeunerweisen (Gypsy Airs), Op. 20	Pablo de Sarasate
Disgust	Caprice No. 2 Caprice No. 7 Caprice No. 13	Niccolò Paganini
Comfort	Canon in D	Johann Pachelbel
	Swan Lake	Pyotr Ilyich Tchaikovsky
	On Wings of Song	Jakob Ludwig Felix Mendelssohn Bartholdy
Surprise	The Symphony No. 94 in G major 2nd movement	Franz Joseph Haydn
	Can-can	Jacques Offenbach
	Concerto No. 2 in G minor, Op. 8, "L'estate" (Summer) 2nd movement	Antonio Vivaldi
Anxiety	The Symphony No. 40 in G minor 1st movement	Wolfgang Amadeus Mozart
	The Butterfly Lovers	Chen Gang and He Zhanhao
	Serenade Melancolique, Op. 26	Pyotr Ilyich Tchaikovsky

4.2 Experimental Results

Experimental results of the proposal are summarized in Table 7. The “Original” shows the number of pieces of violin music that are assigned to six emotion categories, which is determined by questionnaire survey; the “Detected” is the number of accurate recognition results of the proposal; the “False” represents the number of wrong recognition results; the “Precision” is the ratio of “Detected” to “Original”. The overall recognition rate achieved is around 87%.

To give a more detailed explanation of the experimental results. The six basic emotions are further categorized into three levels, i.e., “Positive”, “Neutral”, and “Negative”. Happiness and comfort belong to the “Positive” level; disgust and surprise pertain to the “Neutral” level; sadness and anxiety are assigned to “Negative” level. According to the experiment results, there are two points that can be concluded.

Firstly, recognition rates of positive “Happiness” and positive “Comfort” are better than those of negative “Sadness” and negative “Anxiety”. The possible reason could be, on the one hand, the commonality of positive feelings is higher than that of the negative feelings in general. On the other hand, famous (i.e., familiar to auditory) violin music with sad expression is so frequently performed that the impression of sadness is somewhat suppressed.

As a result, the recognition rate of negative emotional states is not prominent due to the influence of strong subjectivity. It is also noted that, even in the same level, the recognition rates of “Happiness” and “Sadness” are slightly higher than those of “Anxiety” and “Comfort”.

Secondly, as seen in the Table 7, the “Surprise” receives the highest accuracy while the “Disgust” receives the lowest, and both of them belong to the level of neutral. The previous study has drawn a conclusion that the “neutral” is the most difficult emotional state to be recognized (Lee, 2011). The reason for the highest and the lowest could be that the number of music data for them is less than the others. Accordingly, when a false or missing result is yielded, it will significantly impact on the recognition rate.

Table 7: Recognition results of violin music emotion.

Index	Emotion	Original	Detected	False	Precision
1	Happiness	16	15	1	93.75%
2	Sadness	15	13	2	86.67%
3	Disgust	6	4	2	66.67%
4	Comfort	11	10	1	90.91%
5	Surprise	3	3	0	100%
6	Anxiety	9	7	2	77.78%
Total		60	52	8	86.67%

4.3 Application to Background Music Selection for Home Party Scenarios

As a universal language of humanity, the music as well as spoken language is indispensible to achieve casual communication in human-human interaction or even human-robot interaction.

In a home party demonstration, communication between four humans and five eye robots using Mascot Robot System is performed, where there are six scenarios, i.e., Scenario 1: “Greeting guests at the door”, Scenario 2: “Drinking at the mini-bar”, Scenario 3: “Playing dart game”, Scenario 4: “Watching TV”, Scenario 5: “Checking timetable of train at the terminal computer”, and Scenario 6:

"Farewell to guests at the door". Fig. 8 shows a screenshot of Scenario 2.

Figure 8: A screenshot of Scenario 2.

The Fuzzy Atmosfield (Liu et al., 2011) in each scenario is obtained by integrating all the emotional states of participants, namely, humans, robots, and background music. The state of the FA together with its graphical representation is illustrated at the top right corner in Fig. 8.

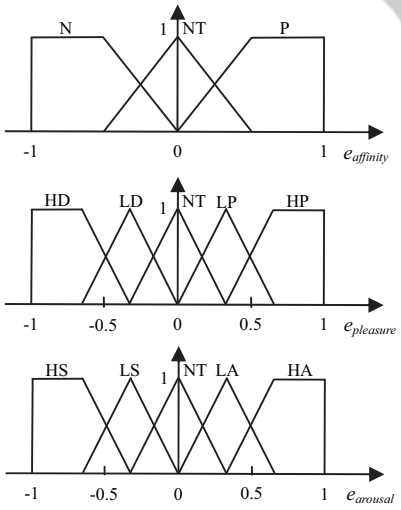

Figure 9: Membership functions for emotion space axes.

Based on the proposed emotion recognition of violin music, violin music emotion is specified in the Affinity-Pleasure-Arousal emotion space. To be convenient to calculate the FA and select appropriate background violin music, fuzzy logic is used to further represent the emotion of violin music. The fuzzy membership functions for the emotion space are shown in Fig. 9, where the fuzzy domain of each axis is defined as [-1, 1], and three linguistic variables are employed for the "Affinity", i.e., Positive (P), Neutral (NT), and Negative (N); five linguistic variables for "Pleasure-Displeasure", i.e., High Pleasure (HP), Low Pleasure (LP), Neutral (NT), Low Displeasure (LD), and High Displeasure (HD); and for "Arousal-Sleep", the linguistic variables are High Arousal (HA), Low Arousal (LA), Neutral (NT), Low Sleep (LS), and High Sleep (HS).

For each scenario, the target state of the FA is predefined beforehand. To achieve it, proper violin music is selected using fuzzy inference, which contains the music emotion that enables the atmosphere change toward the target. The specific violin music chosen for each scenario in the home party is shown in Table 8.

Table 8: Violin music for six scenarios of home party.

Scenario	Violin Music Piece	Emotion		
		Affinity	Pleasure	Arousal
1	Canon in D	NT	LD	NT
2	Minuet in D major	P	LP	LA
3	Humoresque, Op.101 No.7	NT	LP	LS
4	Flight of the Bumblebee	NT	LD	HS
	Turkish March	P	HP	HA
5	String Serenade No.18 in G major 4th	P	LP	LA
6	Salut D'Amour, Op. 12	NT	LD	LS

5 CONCLUSIONS

Emotion recognition of violin music based on the strings music theory is proposed. According to the music theory of "Just Intonation", "Metronome", and "Dynamics", three sets of features of violin music (i.e., harmony, rhythm, and dynamics) are adopted to calculate the values of each axis in the Affinity-Pleasure-Arousal emotion space.

To confirm the validity of the proposed features, 120 pieces of violin music are recorded in a dataset, in which the music emotions are represented by happiness, sadness, comfort, disgust, anxiety, and surprise. Support Vector Regression is used for training the emotion model of violin music with 60 pieces music. The other 60 pieces are used for testing, where the proposal achieves 86.67% average accuracy. The results of "Happiness" and "Comfort" are better than the others since they belong to positive feelings, while the two negative feelings (i.e., "Sadness" and "Anxiety") receive about 83% accuracy. The most difficult-to-perceive neutral feelings, i.e., "Surprise" and "Disgust" obtain the highest and the lowest accuracy, respectively.

Another three features in Table 5, i.e., Articula-

tion, Register, and Timbre, could be used for emotion recognition of violin music in future work. And the proposal could be extended to the emotion recognition of other string instruments such as cello.

Besides the classical music, other types of music can be performed by violin, e.g., folk music, pop music, drawing the violin out of classical shell.

Not limited to the home environment, the proposal could be applied to emotion analysis of background music on other occasions such as café, restaurants, supermarket, bar, and geracomium etc., where an automatic background music recommendation system will be further developed to improve the individual emotion in one-to-one communication or the atmosphere in many-to-many communication.

What's more, it can also be used for medical research such as psychotherapy, where the emotional music is expected to help people eliminate the stress or conquer the other psychological diseases.
