Keywords: Nonlinear MPC, Unmanned Vehicles, Environmental Missions, Water Quality Assessment.

Abstract: Acquiring vast and reliable data of physicochemical parameters is critical to environment monitoring. In the context of water quality analysis, data collection solutions have to overcome challenges related to the scale of environments to be explored. Sites to monitor can be large or remote. These challenges can be approached by the use of Unmanned Vehicles (UVs). Robots provide both flexibility on intervention plans and technological methods for real-time data acquisition. Being autonomous, UVs can explore areas difficult to access or far from the shore. This paper presents a nonlinear Model Predictive Control (MPC) for UV-based exploration. The strategy aims to improve the data collection of physicochemical parameters with the use of an Unmanned Surface Vehicle (USV) targeting water quality analysis. We have performed simulations based on real field experiments with a SPYBOAT® on the Heron Lake in Villeneuve d’Ascq, France. Numerical results suggest that the proposed strategy outperforms the schedule of mission planning and exploration for large areas.

1 INTRODUCTION

The problem that we consider is that of exploration missions, which implies both mission planning and design of autonomous control strategies Nigam (2014). Exploration requires offline and online motion planning, i.e., a sequence of connected linear tracks covering the entire region to explore. In Goerzen et al. (2010) a complete overview of the existing motion planning algorithms is provided. In case the motion planning is solved offline, the parameterized reference allows the USVs to navigate several desired regions by an autonomous control strategy. A popular control technique of growing successes, particularly in the field of MPC, is the path-following problem. A thorough review of Nonlinear MPC trajectory tracking and path-following controllers with application to nonholonomic robots can be found on Nasimnton and Saska (2019). On the other hand, for exploration missions performed by multitarget tracking, there are several control designs adapted for specific environments to provide an energy efficient and robust solution. For instance, Sarunick and Evans (2014) provides a hierarchical MPC that enables an efficient trajectory for the UAVs; a nonlinear MPC scheme for navigation for constrained environment is proposed in Lindqvist et al. (2020); Prodan et al. (2013) (the last paper provide a path design via differential flatness); Bertrand et al. (2014) presents a framework for the cooperative guidance of a fleet of autonomous vehicles with optimal trajectories obtained for an exploration mission on a grid zone. A full discussion about the general relation between different control objectives, covering set-point stabilization, trajectory tracking, path-following and their approaches within the non-
linear MPC framework are included in Matschek et al. (2019). Although interesting, the aforementioned works and the most literature on MPC for exploration are based on set-point stabilization and the benefits of the set-based MPC (i.e., general invariant set stabilization) on the exploration missions have not been explored.

The stabilization of target sets instead of single points is more suitable in cases where it is enough to reach at least one state inside a target region. Such is the case of water resource management, where the exploration mission usually aims to cover large surface of water with an USV to visit regions where a measurement needs to be acquired Anderson et al. (2022).

In this scenario, the properties of invariant sets are useful to provide robustness, flexibility, extension of the domain of attraction, between other benefits. The set stabilization can be framed in the context of set-based MPC Blanchini and Miani (2015); Anderson et al. (2018) where a general invariant set is considered as a control objective.

In this context, the main contribution of this article is to present a novel set-based MPC formulation for nonlinear systems for exploration large areas with an USV. The proposal is based on a set of meshing of the region to be explored with a twofold aims, to configure a simple motion planning offline for the problem and to use the sets composing the meshing as target sets for the controller. Several simulation results targetting water quality assessment show the properties of the proposed controller.

1.1 Notation

We denote with \( \mathbb{N} \) the set of integers, \( \mathbb{N}_0 := \mathbb{N} \cup \{0\} \) and \( I := \{0, 1, \ldots, i\} \). The ceiling function is defined by \( \lceil x \rceil := \min \{ n \in \mathbb{N} : x \leq n \} \). Consider two sets \( \mathcal{U} \subset \mathbb{R}^n \) and \( \mathcal{V} \subset \mathbb{R}^n \), containing the origin and a real number \( \lambda \). The Minkowski sum \( \mathcal{U} \oplus \mathcal{V} \subset \mathbb{R}^n \) is defined by \( \mathcal{U} \oplus \mathcal{V} := \{ u + v : u \in \mathcal{U}, v \in \mathcal{V} \} \); the set \( \mathcal{U} \setminus \mathcal{V} \subset \mathbb{R}^n \) is defined as \( \mathcal{U} \setminus \mathcal{V} := \{ u : u \in \mathcal{U} \land u \neq \mathcal{V} \} \); and the set \( \lambda \mathcal{U} := \{ \lambda u : u \in \mathcal{U} \} \) is a scaled set of \( \mathcal{U} \).

The close ball with center in \( x \in \mathbb{R}^n \) and radius \( \varepsilon > 0 \) is given by \( \mathcal{B}(x, \varepsilon) := \{ y \in \mathbb{R}^n : \| x - y \| \leq \varepsilon \} \). The point \( x \) is an interior point of \( \mathcal{U} \) if there exists \( \varepsilon > 0 \) such that the open ball \( \mathcal{B}(x, \varepsilon) \subset \mathcal{U} \). The interior of a set \( \mathcal{U} \) is the set of all its interior points and it is denoted by \( \text{int} \mathcal{U} \).

2 NONLINEAR SYSTEM AND PRELIMINARY ANALYSIS

The dynamic process discussed in this work consists in the class of discrete-time nonlinear system described by the following equations

\[
\begin{align*}
  x(i+1) &= f(x(i), u(i)), \\
  x(0) &= x_0,
\end{align*}
\]

where \( x(i) \in \mathbb{X} \subset \mathbb{R}^n \) represents the measured states of the system and \( u(i) \in \mathcal{U} \subset \mathbb{R}^m \) the control input at time \( i \). The constraint sets \( \mathcal{X} \) and \( \mathcal{U} \) are compact and convex with the origin inside, and the function \( f : \mathbb{X} \times \mathcal{U} \to \mathbb{X} \) is continuous with \( f(0, 0) = 0 \).

The following definition presents the concept of invariance sets of control.

**Definition 1** (Control Invariant Set - CIS). The set \( \mathcal{X} \subset \mathbb{X} \) is a control invariant set (CIS) for system (1) if for all \( x \in \mathcal{X} \) there exists \( u \in \mathcal{U} \) such that \( f(x, u) \in \mathcal{X} \).

The CIS has an associated corresponding input set given by

\[
\Psi(\mathcal{X}) := \{ u \in \mathcal{U} : \exists x \in \mathcal{X} \text{ such that } f(x, u) \in \mathcal{X} \},
\]

meaning that every input on \( \Psi(\mathcal{X}) \) leaves at least one state of \( \mathcal{X} \) inside \( \mathcal{X} \).

A CIS is called a Contractive CIS if the condition on Definition 1 is replaced by: for every \( x \in \mathcal{X} \) there is \( u \in \mathcal{U} \) such that \( f(x, u) \in \text{int} \mathcal{X} \).

3 SET-BASED MPC

A generalization of the MPC controller for tracking invariant sets is presented. The idea is to track and reach sets that not only include stationary states, but also transient states. We start with a quite general formulation, that is particularized in the next subsections to different applicable cases. Also consider the following definition.

**Definition 2** (Generalized Distance Stage Cost Function). A generalized distance function \( d(x, \mathcal{X}) \), from \( x \) to the CIS \( \mathcal{X} \), is a function with the following properties: (1) \( d(x, \mathcal{X}) \) is convex and continuous for all \( x \in \mathcal{X} \), (2) \( d(x, \mathcal{X}) = 0 \) for all \( x \in \mathcal{X} \), (3) \( d(x, \mathcal{X}) > 0 \) for all \( x \in \mathcal{X} \setminus \mathcal{X} \).

The proposed controller cost function will be given by:

\[
V_N(x, \mathcal{X}, \mathcal{U}) = \sum_{j=0}^{N-1} \alpha d(x_j, \mathcal{X}) + \beta d(u_j, \Psi(\mathcal{X})) ,
\]

where \( x \in \mathbb{X} \subset \mathbb{R}^n \) represents the measured states of the system and \( u \in \mathcal{U} \subset \mathbb{R}^m \) the control input at time \( i \). The constraint sets \( \mathcal{X} \) and \( \mathcal{U} \) are compact and convex with the origin inside, and the function \( f : \mathbb{X} \times \mathcal{U} \to \mathbb{X} \) is continuous with \( f(0, 0) = 0 \).
where $\alpha$ and $\beta$ are positive real numbers, $N$ is the prediction horizon, the initial state $x = x_0$, the predicted states $x_{j+1} = f(x_j, u_j)$ and the input sequence $u = \{u_0, \cdots, u_{N-1}\}$.

**Remark 3.** The usual terminal cost associated with the terminal predicted state $x_N$ can be omitted on Eq. (2) if $x_N$ is force to belong to the set $\Omega$, i.e., $d(x_N, \Omega) = 0$. As usual in MPC design, a local control action $\delta$ that will act for predictions inside the terminal set $\Omega$ will have also null cost since $\delta \in \Psi(U)$.

The general set-based MPC is given by the following optimization problem solved at each sample time $k \in \mathbb{N}$.

$$\min_{u_k}(x, \Omega, u)$$

s.t. $x_0 = x,
\begin{align*}
x_{j+1} &= f(x_j, u_j), & j \in I_{N-1}, \\
x_j &\in \mathbb{X}, & u_j \in U, & j \in I_{N-1}, \\
x_N &\in \Omega
\end{align*}
$$

Taking into account the receding horizon policy, the control law at time $k$ is given by the first element of the optimal sequence $u^*$ of the optimization problem given by (3) solved at time $k$.

Consider the next Lemma for the asymptotic stability of the closed-loop system.

**Lemma 4.** If $\Omega \subset \mathbb{X}$ is a CIS for system (1) in the cost function (2), then $\Omega$ is asymptotically stable for the closed-loop system (1) controlled by the set-based MPC given by (3).

**Proof.** The proof can be found on Blanchini and Miani (2015). It is stated that under the hypothesis of the Lemma there is a Lyapunov function (given by the optimal cost $V_0^*(\cdot)$) that is a decreasing function on the level sets of the generalized distance function used on the function cost.

Next section presents an extension of the set-based MPC to tracking multi-target sets.

### 3.1 Multi-target Tracking

Consider now that the closed-loop system has to reach every element on the set $\bar{\Omega} = \{\Omega_1, \Omega_2, \cdots, \Omega_K\}$ with $\Omega_i \subset \mathbb{X}$ for $i = 1, \cdots, K$, in the specified order. This is, once the controlled system reaches the target set $\Omega_i \in \bar{\Omega}$, the objective change to $\Omega_{i+1}$ and so on until the state of the system converge to $\Omega_K$. Clearly, a condition must be establish in order to switch target every time the current target is reached. Here a state-dependent MPC will be used to decide when a target set is considered a reached set (according the position of the current state). Consider the following definition.

**Definition 5** (Reached set). The first set on $\bar{\Omega}$, i.e., $\Omega_1$ is considered a reached set if $x(i) \in \Omega_1$ for some $i > 0$. For $k > 1$, the target set $\Omega_k \in \bar{\Omega}$ is considered a reached set if $x(i) \in \Omega_k$ for some $i > 0$ and the previous sets $\Omega_1, \cdots, \Omega_{k-1}$ are reached sets.

As it can be seen, the condition for a set on $\bar{\Omega}$ to be a reached set is defined inductively.

The current target set, $\Omega_k$, which it depends on the position of the current state $x = x(i)$ is given by the definition.

**Definition 6** (Current target set). Given the states of the closed-loop system $x(i) \in \mathbb{X}$ for $i = 0, \cdots, k$, where $x = x(k)$ is the current state at time $k$. The current target set, $\Omega_k$, is given by

$$\Omega_k := \{\Omega_{k+1} : k = \max\{i : \Omega_i \text{ is a reached set}\}\}$$

In the case that there is not reached sets then $\Omega_k := \emptyset$.

$\Omega_k$, for $x = x(k)$, it defines the current objective on time $k$.

The following MPC formulation to track sets is based on the formulation presented on Limon et al. (2005). The approach of this mentioned work was to track sets with the aim of extends the domain of attraction of the controller.

Considering the control law derived from solving by the receding horizon strategy the following optimization problem.

$$\min_{u_k}(x, \Omega_k, u)$$

s.t. $x_0 = x,
\begin{align*}
x_{j+1} &= f(x_j, u_j), & j \in I_{N-1}, \\
x_j &\in \mathbb{X}, & u_j \in U, & j \in I_{N-1}, \\
x_N &\in \Omega_k
\end{align*}
$$

For an asymptotic stability condition consider the next Lemma.

**Lemma 7.** If $\Omega_j \in \Omega$ is a Contractive CIS for all $j = 1, \cdots, K$, then every $\Omega_j \in \Omega$ is a reached set for the closed-loop system controlled by the MPC given on (5).

**Proof.** If the current target set $\Omega_k = \Omega_j$ is a Contractive CIS for system (1), the results proposed on Anderson et al. (2018) proves that the closed-loop system will reach in finite-time the set $\Omega_k$. Therefore, according the formulation, once the target set $\Omega_j$ is reached, the current state switch to $\Omega_k = \Omega_{j+1}$. The proof is concluded by induction. □
The following section provides the main result of the paper. The proposal is an extension of the above MPC formulation that aims to improve the performance of the controlled trajectory.

4 PROPOSED MPC

In this section, the MPC based on sets for tracking multi-target set is extended to improve performance. To this end a dual-MPC is formulated, where the goal of the first mode is to reach only the current target set \( \Omega \), the second mode is activated when the current state \( x \) is close enough of \( \Omega \). This model aims to give more importance to the target set that became next, i.e., \( \Omega_{t+1} \).

To trigger the second mode the current state must be close enough of \( \Omega \). This condition can be stated by the inclusion of the current state on the fattening set of \( \Omega \).

Definition 8 (Fattening set). Let \( \Omega \subset \mathbb{R}^n \) be the current target set of control, and let \( \varepsilon > 0 \), we denote the \( \varepsilon \)-fattening set of \( \Omega \) by
\[
(\Omega)\varepsilon := \{ x \in \mathbb{R}^n : x \in \Omega \}.
\]

Remark 9. The term ‘close enough’ of the current target set is a parameter of the control design and can be selected by chosen an appropriate \( \varepsilon \).

The second mode is activated when the current state is on \( (\Omega)\varepsilon \); at this time the design of the controller considers the next target set, i.e. if \( \Omega = \Omega_j \) then the next target set is \( \Omega_{j+1} \). The following properly defines the second target set, \( \Omega_j^+ \):

\[
\Omega_j^+ := \begin{cases} 
\Omega_{j+1}, & \text{if } \Omega_j = \Omega_k, \\
\Omega_j, & \text{otherwise}
\end{cases}
\]

(6)

Note that, if the current state \( x \notin (\Omega)\varepsilon \), then it is considered that \( \Omega_j^+ = \Omega \). This detail allows to formulate the problem in a consistent way.

Consider now the function \( N_\varepsilon : \mathbb{X} \rightarrow I_N \) that defines the prediction horizon of the proposed controller:

\[
N_\varepsilon := \begin{cases} 
\text{ceil}(\frac{\|d(x)\|}{N_\varepsilon}), & x \in (\Omega)\varepsilon \\
0, & \text{otherwise}
\end{cases}
\]

(7)

Note that for the first mode, i.e. when \( x \notin (\Omega)\varepsilon \), the prediction horizon is \( N \). For the second mode, i.e. when \( x \in (\Omega)\varepsilon \), the prediction horizon decreases with the distance of the current state \( x \) to the current target set. The ceil(·) function is considered for \( N_\varepsilon \) to be an integer number.

Remark 10. Function \( N_\varepsilon \) is a decreasing function with maximum value when \( x \) belongs to the boundary of \( (\Omega)\varepsilon \), given by \( N_\varepsilon = N \); and a minimum value when \( x \in \Omega \), given by \( N_\varepsilon = 0 \).

The second mode computes \( N_\varepsilon \) predictions to minimize the distance of the states to \( \Omega \), and \( N - N_\varepsilon \) predictions to minimize the distance of the states to \( \Omega^+ \).

The cost function is given by
\[
J_N(x; u) = \sum_{j=0}^{N-1} p\ell_\Omega(x_j, u_j) + \sum_{j=N_\varepsilon}^{N-1} q\ell_\Omega(x_j, u_j) \quad (7)
\]

where \( \ell_\Omega(x_j, u_j) := \alpha_d(x_j, \Omega) + \beta_d(u_j, \Psi(\Omega)) \), and \( p, q > 0 \) are weight values.

The nonlinear MPC is given by the following optimization problem solved at each sample time \( i \in N \).

\[
\min_u J_N(x; u) \quad (8)
\]

s.t. \( x_0 = x \), \( x_{j+1} = f(x_j, u_j), \quad j \in I_{N-1} \), \( x_j \in \mathbb{X}, \quad u_j \in \mathbb{U}, \quad j \in I_{N-1} \), \( x_{N_\varepsilon} \in \Omega \), \( x_N \in \Omega^+ \).

The solution of Problem (8) is the optimal control sequence \( u^0 = \{u_0^0, u_1^0, \ldots, u_{N-1}^0\} \). Taking into account the receding horizon policy, the control law at time \( i \) is given by \( \kappa = u_0^i \) (the first element of the optimal control sequence), which is applied to the real plant at every time step \( i \).

4.1 Some Quantitative Properties of the Proposal

In what follows, some numerical results are shown to clarify the nontrivial properties of the proposed controller.

We consider the USV model represented by Eq. (9). With abuse of notation let define the current state of the vessel by

\[
x(i) = (x, y, u, v, r),
\]

for every time \( i \geq 0 \). Where \( x, y, z \) represent position states, on the surface \( (x, y) \) and \( \psi \) is the ‘direction position’ of the vehicle in the inertial frame. Meanwhile \( u, v, r \) represent the velocities states, i.e., surge (forward), sway (perpendicular) and yaw (angular), respectively.

The first simulations attempt to show the anticipatory behaviour of the proposed control. Consider the paths given by \( \Omega = \{\Omega_1, \ldots, \Omega_5\} \) and \( \Psi = \{\Psi_1, \ldots, \Psi_5\} \) on the surface of the water (see Fig. 1). This two paths are a reflection of each other.
5 SPYBOAT®’S DESCRIPTION

In this section the description of the USV used on the simulation results and the real experiment described on Section 6 is presented.

The CT2MC company has designed a range of vessels dedicated to answer the need of data monitoring of freshwater resource. The SPYBOAT® technology follows standard equipment configuration including multiple sensors (localization system, compass, sonar, camera) and is propelled by two independent actuators. Thus the heading is controlled through a differential thrust method.

The USV is equipped with a Hyperion optical sensor from Valeport, for the measurement of the turbidity. It is also equipped with Tripod sensors from AquaLabo to measure the temperature, Dissolved Oxygen, pH, and conductivity.

5.1 USV Nonlinear System

In Hervagault (2019) a kinematic model for the SPYBOAT® vessel was identified based following standard assumptions.

The marine craft moves on an horizontal plane and only surge, sway and yaw are considered. The resulting is a nonlinear model given by the following equations.

\[
\begin{align*}
\dot{x} &= u \cos(\psi) - v \sin(\psi), \\
\dot{y} &= u \sin(\psi) + v \cos(\psi), \\
\dot{\psi} &= r, \\
\dot{u} &= \frac{m_1}{m_1} u + \frac{m_2}{m_1} v + \frac{N_x}{m_1} u, \\
\dot{v} &= -\frac{m_1}{m_2} u^2 + \frac{v}{m_2} v, \\
\dot{r} &= \frac{m_1}{m_3} + \frac{m_2}{m_3} u + \frac{N_y}{m_3} r
\end{align*}
\]

(9)

The vector \((x, y)\) is the position on the surface and \(\psi\) the direction of the vessel, \(u, v, r\) are the surge, sway and yaw velocities respectively. The inputs are given by \(\tau_u = F_1 + F_2\) and \(\tau_r = b(F_1 - F_2)\), where \(F_1\) and \(F_2\) are the port side and starboard side thrust forces, and \(b\) represent 1/2 of the distance between thrusters. The parameter \(X_u, Y_u\) and \(N\) are the linear drag coefficient in surge direction from surge, the linear drag coefficient in sway direction from yaw rate and the linear drag moment coefficient from yaw rate, respectively. The mass parameters \(m_{ij}\) include added mass contributions that represent hydraulic pressure forces and torque due to forced harmonic motion of the vessel.
which are proportional to acceleration:
\[
m_{11} = m + 0.05m, \\
m_{22} = m + 0.5(\rho \pi D^2 L), \\
m_{33} = m(L^2 + W^2) + 0.5(0.1mB^2 + \rho \pi D^2 L^3) / 12,
\]
where \( m \) is the actual mass, \( L \) is the effective length (hull’s length in the water), \( W \) is the width, \( D \) is the mean submerged depth, \( B \) is the distance between propellers and \( \rho \) is the water density. 

For more detail on the parameters of model (9) see Hervagault (2019).

6 ENVIRONMENTAL MISSION

In this section some simulation results for exploration mission targeting water quality map extraction are presented. First, the problem statement and the general objective of the mission are explained.

6.1 Problem Statement

In Anderson et al. (2022), a data collection of physicochemical parameters (such as pH, turbidity, conductivity, temperature and dissolved oxygen) that indicate the pollution index of water surface were studied in a particular region of the Heron Lake in Villeneuve d’Ascq, France (see region \( \Omega \) on Fig. 3). In this artificial lake the water arrives from east and when the level is too high water is pumped out to a nearby river in the far western point. A natural remediation of the water occurs in lake so a gradient of the parameters can be expected between points on the entrance with a high biodegradable inputs Ivanovsky et al. (2018).

Remark 11 (General Objective). In this context - as was explain on Anderson et al. (2022) - the general objective is to construct a limnological map of the region \( \Omega \), i.e., a map \( F : \Omega \rightarrow \mathbb{R}^2 \) such that \( F \) assigns to every point on \( \Omega \) its approximation value of pH, turbidity, conductivity, temperature and dissolved oxygen (see Fig. 5 for dissolved oxygen).

The construction of map \( F \) on the region of interest was discussed on Anderson et al. (2022), where an approximation of \( F \) was proposed by geo-statistical interpolation methods based on real measurements provided by a hand-operated USV. The interpolation method was necessary at this point in order to complete uncovered points (unmeasured positions) due to the irregularity of the hand-operated trajectory (see Fig. 4).

To improve the data collection of the aforementioned physicochemical parameters, in what follows the proposed control strategy is performed for a regular exploration of region \( \Omega \).

6.2 Motion Planning

The area of interest \( \Omega \) was computed by the largest convex set containing the entire data collection of Fig. 5. The design of the path to explore the complete region is based on a regular map meshing of \( \Omega \). The meshing consists in a collection of disjointed sets \( \{ \Omega_j \}_{j=1}^K \) such that \( \bigcup \Omega_j \) contains the region \( \Omega \). The size of every \( \Omega_j \) must be considered according the size of the vessel, the accurate of the map \( F \), the time for the exploration mission, etc. On the other hand, the shape of \( \Omega_j \) must be chosen according the best performance of the controller. Figure 6 shows a motion planning for squares \( \Omega_j \) with a size of 100m². A discussion about the shapes and sizes of the meshing is discussed on Anderson et al. (2022)

The controlled vessel reaches every set \( \Omega_j \) and performs a direct in situ measurement of each parameters. The limnological map \( F \) is constructed by this process.

Remark 12. The path \( \bar{\Omega} = \{ \Omega_1, \ldots, \Omega_K \} \) is an ordered sequence that determines in which order the target sets \( \Omega_j \) are reached. According to the meshing considered in this work, there are several possible
Figure 5: Limnological map $F$ on $\Omega$ for the Dissolved Oxygen (Anderson et al., 2022).

Figure 6: A motion planning to explore $\Omega$.

Figure 7: Controlled trajectory for exploring region $\Omega$.

6.3 Exploring Results

Fig. 7 shows the application of the proposed MPC with a prediction horizon $N = 15$, a discretization of the dynamical model (9) with discrete-time with $T = 1$ seg and initial state $x(0) = (x, y, \psi, u, v, r) = (20, 105, -\frac{\pi}{2}, 0, 0, 0)$. To explore region $\Omega$ a regular meshing of squares with a size of 25m$^2$ is used. Every target set $\Omega_j$ share an edge with the next target set $\Omega^+_j$, so once the system enter into $\Omega_j$, only the second mode of the MPC (8) is used (the first mode is only used at the beginning to reach $\Omega_1$). Fig. 7 shows the controlled trajectory that reach every target set $\Omega_j$ at least one time.

In order to construct the map $F$ by direct in situ measurements of each parameters inside every target set $\Omega_j$, the velocity $u$ of the vessel must belongs to certain range to allows the sensor to take every measurement inside $\Omega_j$ for all $j = 1, \ldots, K$. This can be approach by considering target sets of three dimensions, i.e. if $z = (x, y, \psi, u, v, r)$

$$
\Omega_j = \{z \in \mathbb{R}^6 : l_x \leq x \leq u_x, l_y \leq y \leq u_y, \ldots, l_u \leq u \leq u_u, \infty \leq \psi, v, r \leq \infty \}.
$$

Note that there is no consideration to minimize states $\psi, v$ and $r$, which means that they are free. For the simulations on Fig. 8 we consider that $1 \leq u \leq 2$ for all $\Omega_j$, $j = 1, \ldots, K$, i.e., proj$_u \Omega_j = [1, 2]$ for all $j$. The figure shows the velocity state and inputs for the time interval $[0, 100]$. On the other hand, for the simulations on Fig. 9 the target set for the velocity is $0.5 \leq u \leq 1.5$. For all $\Omega_j$, $j = 1, \ldots, K$, i.e., proj$_u \Omega_j = [0.5, 1.5]$ for all $j$.

Figure 8: Inputs and velocity state for the target set proj$_u \Omega_j = [1, 2]$.

Remark 13. Simulation results suggest that the exploration of the region of interest $\Omega$ can be done with a very simple motion planning and with an optimal trajectory that reaches every point on the surface where a measurement needs to be performed. Even more, the velocity of the vessel can be selected for every target $\Omega_j$ with $j = 1, \ldots, K$ according the requirements of the experiment. However, more simulation experiments need to be done before the real implementation, but they are out of the scope of this work.
7 CONCLUSION

Environmental missions were performed on Heron Lake in Villeneuve d’Ascq, France. The main goal of the experiment is to construct a temporal water quality profile of a region of the lake, where there is a suspicion of a source of pollution, so more experiments are expected in the same region. To outperform the data collection results, in this paper a nonlinear MPC for USV for exploration was presented. The strategy shows that a simple schedule of mission planning can be obtained, and the simulations proves that large water surfaces can be tracked in an optimal and flexible way. This results are expected to outperform the real exploration of large areas targeting data collection for water quality analysis.
